## Abstract

41 An increasing number of applications are being constructed by combining or coordinating the  
42 execution of multiple Web services, each of which may represent an interface to a different  
43 underlying technology. The resulting applications can be very complex in structure, with complex  
44 relationships between their constituent services. Furthermore, the execution of such an  
45 application may take a long time to complete, and may contain long periods of inactivity, often  
46 due to the constituent services requiring user interactions. In the loosely coupled environment  
47 represented by Web services, long running applications will require support for recovery and  
48 compensation, because machines may fail, processes may be cancelled, or services may be  
49 moved or withdrawn. Web services transactions also must span multiple transaction models and  
50 protocols native to the underlying technologies onto which the Web services are mapped.

51 A common technique for fault-tolerance is through the use of atomic transactions, which have the  
52 well know ACID properties, operating on persistent (long-lived) objects. Transactions ensure that  
53 only consistent state changes take place despite concurrent access and failures. However,  
54 traditional transactions depend upon tightly coupled protocols, and thus are often not well suited  
55 to more loosely-coupled Web services based applications, although they are likely to be used in  
56 some of the constituent technologies. It is more likely that traditional transactions are used in the  
57 minority of cases in which the cooperating Web services can take advantage of them, while new  
58 mechanisms, such as compensation, replay, and persisting business process state, more suited  
59 to Web services are developed and used for the more typical case.

## 91 1 Note on terminology

92 The keywords "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD",  
93 "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be  
94 interpreted as described in RFC2119 [2].

95 Namespace URIs of the general form <http://example.org> and <http://example.com> represents some  
96 application-dependent or context-dependent URI as defined in RFC 2396 [3].

### 97 1.1 Namespace

98 The XML namespace URI that MUST be used by implementations of this specification is:

99 `http://docs.oasis-open.org/wscaf/2005/03/wsacid`

#### 100 1.1.1 Prefix Namespace

Prefix	Namespace
wscf	<a href="http://docs.oasis-open.org/wscaf/2005/02/wscf">http://docs.oasis-open.org/wscaf/2005/02/wscf</a>
wsctx	<a href="http://docs.oasis-open.org/wscaf/2004/09/wsctx">http://docs.oasis-open.org/wscaf/2004/09/wsctx</a>
wsacid	<a href="http://docs.oasis-open.org/wscaf/2005/07/wsacid">http://docs.oasis-open.org/wscaf/2005/07/wsacid</a>
ref	<a href="http://docs.oasisopen.org/wsrn/2004/06/reference-1.1">http://docs.oasisopen.org/wsrn/2004/06/reference-1.1</a>
wsdl	<a href="http://schemas.xmlsoap.org/wsdl/">http://schemas.xmlsoap.org/wsdl/</a>
xsd	<a href="http://www.w3.org/2001/XMLSchema">http://www.w3.org/2001/XMLSchema</a>
wsu	<a href="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-utility-1.0.xsd">http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-utility-1.0.xsd</a>
tns	targetNamespace

**Comment:** Kevin, can you check these are right (dates)?

### 101 1.2 Referencing Specifications

102 One or more other specifications may reference the WS-ACID specification. The usage of  
103 optional items in WS-ACID is typically determined by the requirements of such as referencing  
104 specification.

105 A referencing specification generally defines the protocol types based on WS-ACID. Any  
106 application that uses WS-ACID must also decide what optional features are required. For the  
107 purpose of this document, the term *referencing specification* covers both formal specifications  
108 and more general applications that use WS-ACID.

### 109 1.3 Precedence of schema and WSDL

110 Throughout this specification, WSDL and schema elements may be used for illustrative or  
111 convenience purposes. However, in a situation where those elements within this document differ  
112 from the separate WS-Context WSDL or schema files, it is those files that have precedence and  
113 not this specification.

114

115

116

## 2 Architecture

117

*Atomic transactions* are a well-known technique for guaranteeing consistency in the presence of failures [10]. The ACID properties of atomic transactions (Atomicity, Consistency, Isolation, and Durability) ensure that even in complex business applications consistency of state is preserved, despite concurrent accesses and failures. This is an extremely useful fault-tolerance technique, especially when multiple, possibly remote, resources are involved.

122

WS-ACID leverages the WS-CF and WS-Context specifications. Figure 4 illustrates the layering of WS-ACID onto WS-CF. WS-ACID defines a pluggable transaction protocol that can be used with the coordinator to negotiate a set of actions for all participants to execute based on the outcome of a series of related Web services executions. The executions are related through the use of shared context. Examples of coordinated outcomes include the classic two-phase commit protocol, a three phase commit protocol, open nested transaction protocol, asynchronous messaging protocol, or business process automation protocol.

123

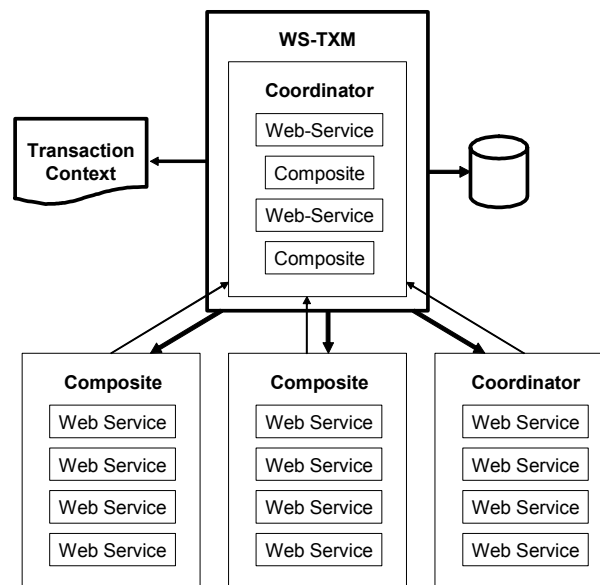

124

125

126

127

128

129

130

**Figure 1, Relationship of transactions to coordination framework.**

131

Coordinators can be participants of other coordinators, as shown above. When a coordinator registers itself with another coordinator, it can represent a series of local activities and map a neutral transaction protocol onto a platform-specific transaction protocol.

133

134

### 2.1 Invocation of Service Operations

135

How application services are invoked is outside the scope of this specification: they MAY use synchronous or asynchronous message passing.

136

137

Irrespective of how remote invocations occur, context information related to the sender's activity needs to be referenced or propagated. This specification determines the format of the context, how it is referenced, and how a context may be created.

138

139

140 In order to support both synchronous and asynchronous interactions, the components are  
141 described in terms of the behavior and the interactions that occur between them. All interactions  
142 are described in terms of correlated messages, which a referencing specification MAY abstract at  
143 a higher level into request/response pairs.

144 Faults and errors that may occur when a service is invoked are communicated back to other Web  
145 services in the activity via SOAP messages that are part of the standard protocol. To achieve this,  
146 the fault mechanism of the underlying SOAP-based transport is used. For example, if an  
147 operation fails because no activity is present when one is required, then the callback interface will  
148 receive a SOAP fault including type of the fault and additional implementation specific information  
149 items supported the SOAP fault definition. WS-Context specific fault types are described for each  
150 operation. A fault type is communicated as an XML QName; the prefix consists of the WS-  
151 Context namespace and the local part is the fault name listed in the operation description.

152 Note, a transientFault message is produced when the implementation finds it  
153 cannot successfully execute the requested operation at that time from some  
154 *temporary* reason. This reason may be implementation or referencing  
155 specification specific. A receiver of a transientFault is free to retry the operation  
156 which originally generated it on the assumption that eventually a different  
157 response will be produced. Sub-types of transientFault MAY be further defined  
158 using the fault model described which can allow for the communication of more  
159 specific information on the type of fault.

160 As long as implementations ensure that the on-the-wire message formats are compliant with  
161 those defined in this specification, how the end-points are implemented and how they expose the  
162 various operations (e.g., via WSDL [1]) is not mandated by this specification. However, a  
163 normative WSDL binding is provided by default in this specification.

164 Note, this specification does not assume that a reliable message delivery  
165 mechanism has to be used for message interactions. As such, it MAY be  
166 implementation dependant as to what action is taken if a message is not  
167 delivered or no response is received.

## 168 **2.2 Relationship to WSDL**

169 Where WSDL is used in this specification it uses one-way messages with callbacks. This is the  
170 normative style. Other binding styles are possible (perhaps defined by referencing specifications),  
171 although they may have different acknowledgment styles and delivery mechanisms. It is beyond  
172 the scope of WS-ACID to define these styles.

173 Note, conformant implementations MUST support the normative WSDL defined  
174 in the specification where those respective interfaces are required. WSDL for  
175 optional components in the specification is REQUIRED only in the cases where  
176 the respective components are supported.

177 For clarity WSDL is shown in an abbreviated form in the main body of the document: only  
178 portTypes are illustrated; a default binding to SOAP 1.1-over-HTTP is also assumed as per [1].

## 179 **2.3 Referencing and addressing conventions**

180 There are multiple mechanisms for addressing messages and referencing Web services currently  
181 proposed by the Web services community. This specification defers the rules for addressing  
182 SOAP messages to existing specifications; the addressing information is assumed to be placed in  
183 SOAP headers and respect the normative rules required by existing specifications.

184 However, the Coordination Framework message set requires an interoperable mechanism for  
185 referencing Web Services. For example, context structures may reference the service that is used  
186 to manage the content of the context. To support this requirement, WS-CAF has adopted an open  
187 content model for service references as defined by the Web Services Reliable Messaging  
188 Technical Committee [5]. The schema is defined in [6][7] and is shown in Figure 1.

```
189 <xsd:complexType name="ServiceRefType">
190   <xsd:sequence>
191     <xsd:any namespace="##other" processContents="lax"/>
192   </xsd:sequence>
193   <xsd:attribute name="reference-scheme" type="xsd:anyURI"
194     use="optional"/>
195 </xsd:complexType>
```

196 Figure 2, service-ref Element

197 The ServiceRefType is extended by elements of the context structure as shown in Figure 2.

```
198 <xsd:element name="context-manager" type="ref:ServiceRefType"/>
```

199 Figure 3, ServiceRefType example.

200 Within the **ServiceRefType**, the reference-scheme is the namespace URI for the referenced  
201 addressing specification. For example, the value for WSRef defined in the WS-MessageDelivery  
202 specification [4] would be <http://www.w3.org/2004/04/ws-messagedelivery>. The value for WSRef  
203 defined in the WS-Addressing specification [8] would be  
204 <http://schemas.xmlsoap.org/ws/2004/08/addressing>. The reference scheme is optional and need  
205 only be used if the namespace URI of the QName of the Web service reference cannot be used  
206 to unambiguously identify the addressing specification in which it is defined.

207 Messages sent to referenced services **MUST** use the addressing scheme defined by the  
208 specification indicated by the value of the reference-scheme element if present. Otherwise, the  
209 namespace URI associated with the Web service reference element **MUST** be used to determine  
210 the required addressing scheme. A service that requires a service reference element **MUST** use  
211 the `mustUnderstand` attribute for the SOAP header element within which it is enclosed and **MUST**  
212 return a `mustUnderstand` SOAP fault if the reference element isn't present and understood.

213 Note, it is assumed that the addressing mechanism used by a given  
214 implementation supports a reply-to or sender field on each received message so  
215 that any required responses can be sent to a suitable response endpoint. This  
216 specification requires such support and does not define how responses are  
217 handled.

218 To preserve interoperability in deployments that contain multiple addressing schemes, there are  
219 no restrictions on a system, beyond those of the composite services themselves. However, it is  
220 **RECOMMENDED** where possible that composite applications confine themselves to the use of  
221 single addressing and reference model.

222 Because the prescriptive interaction pattern used by WS-ACID is based on one-way messages  
223 with callbacks, it is possible that an endpoint may receive an unsolicited or unexpected message.  
224 The recipient is free to do whatever it wants with such messages.

225

## 3 WS-ACID

226 The *ACID transaction* model recognizes that Web Services are for interoperability as much as for  
227 the Internet. As such, interoperability of existing transaction processing systems will be an  
228 important part of Web Services Transaction Management: such systems already form the  
229 backbone of enterprise level applications and will continue to do so for the Web Services  
230 equivalent. Business-to-business activities will typically involve back-end transaction processing  
231 systems either directly or indirectly and being able to tie together these environments will be the  
232 key to the successful take-up of Web Services transactions.

233 Although ACID transactions may not be suitable for all Web Services, they are most definitely  
234 suitable for some, and particularly high-value interactions such as those involved in finance. As a  
235 result, the ACID transaction model has been designed with interoperability in mind. Within this  
236 model it is assumed that all services (and associated participants) provide ACID semantics and  
237 that any use of atomic transactions occurs in environments and situations where this is  
238 appropriate: in a trusted domain, over short durations.

239 In the ACID model, each activity is bound to the scope of a transaction, such that the end of an  
240 activity automatically triggers the termination (commit or rollback) of the associated transaction.

241 The coordinator-type URI for the ACID transaction model is  
242 <http://www.webservicestransactions.org/wsd/wstxm/tx-acid/2003/03>

Comment: Update.

### 243 3.1 Restrictions imposed on using WS-CF

244 As a Referencing Specification, the WS-ACID transaction model imposes the following  
245 restrictions on using WS-CF:

- 246 • It is illegal to attempt to remove a participant from a transaction at any time. When the  
247 transaction terminates, participants are implicitly removed. As such, any attempt to call  
248 *removeParticipant* will result in the *wrongState* error message being returned.

### 249 3.2 Two-phase commit

250 The ACID transaction model uses a traditional two-phase commit protocol [2] with the following  
251 optimizations:

- 252 • *Presumed rollback*: the transaction coordinator need not record information about the  
253 participants in stable storage until it decides to commit, i.e., until after the prepare phase  
254 has completed successfully.
- 255 • *One-phase*: if the coordinator discovers that only a single participant is registered then it  
256 SHOULD omit the prepare phase..
- 257 • *Read-only*: a participant that is responsible for a service that did not modify any  
258 transactional data during the course of the transaction can indicate to the coordinator  
259 during prepare that it is a *read-only participant* and the coordinator SHOULD omit it from  
260 the second phase of the commit protocol.

261 Participants that have successfully passed the *prepare* phase are allowed to make autonomous  
262 decisions as to whether they commit or rollback. A participant that makes such an autonomous  
263 choice *must* record its decision in case it is eventually contacted to complete the original  
264 transaction. If the coordinator eventually informs the participant of the fate of the transaction and  
265 it is the same as the autonomous choice the participant made, then there is obviously no  
266 problem: the participant simply got there before the coordinator did. However, if the decision is  
267 contrary, then a non-atomic outcome has happened: a *heuristic outcome*, with a corresponding  
268 *heuristic decision*.

269 The possible heuristic outcomes are:

- 270 • *Heuristic rollback*: the commit operation failed because some or all of the participants  
271 unilaterally rolled back the transaction.
- 272 • *Heuristic commit*: an attempted rollback operation failed because all of the participants  
273 unilaterally committed. This may happen if, for example, the coordinator was able to  
274 successfully prepare the transaction but then decided to roll it back (e.g., it could not  
275 update its log) but in the meanwhile the participants decided to commit.
- 276 • *Heuristic mixed*: some updates were committed while others were rolled back.
- 277 • *Heuristic hazard*: the disposition of some of the updates is unknown. For those which are  
278 known, they have either all been committed or all rolled back.

### 279 3.2.1 WS-ACID and WS-Context message interactions

280 WS-ACID is a referencing specification for WS-CF and hence leverages the *activity group*  
281 concept. When an application creates a new activity group (by sending a **wsctx:begin** message  
282 to the relevant Context Service), an associated WS-ACID coordinator MAY be created in the  
283 Active state, as shown in [Figure 4](#).

Deleted: Figure 4

284 Note, participants enlisted with a WS-ACID activity group progress through the  
285 same state transitions.

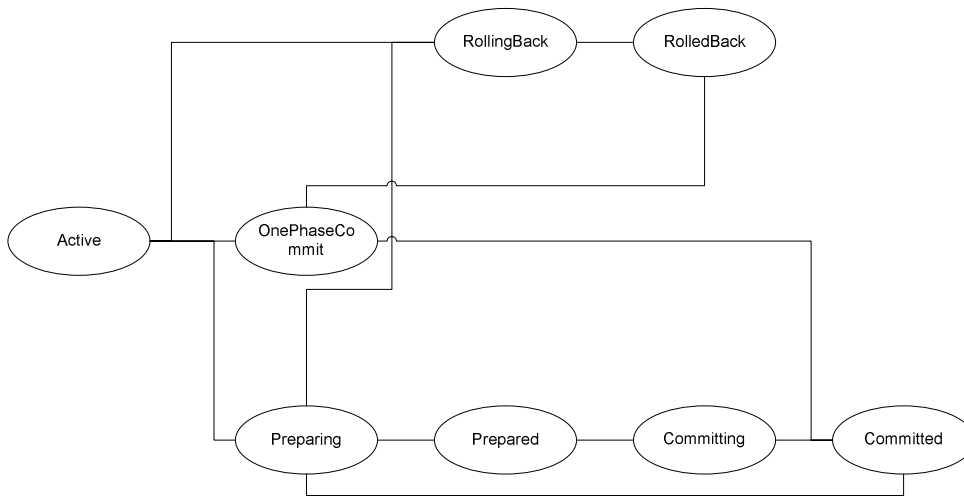

286 The coordinator has the lifetime period associated with the activity: if the activity timeout elapses  
287 before the activity has terminated, then the transaction will be terminated in the *RolledBack* state.

288 A transactional activity can either be committed or rolled back via the **wsctx:complete** message.  
289 The protocol-specific termination extension within the **wsctx:complete** message contains either  
290 the **wsacid:Commit** or **wsacid:Rollback** completion code, depending upon whether the  
291 transaction is to be committed or rolled back respectively.

292 If the transaction is instructed to commit then the application sends an appropriate  
293 **wsctx:complete** message to the Context Service. If there is only a single participant enrolled  
294 with the transaction then the coordinator SHOULD use the one-phase commit optimization. As  
295 such, the coordinator begins the *OnePhaseCommit* protocol and either transits to the *RolledBack*  
296 or *Committed* state, depending upon the result returned by the participant.

297 If there are multiple participants enrolled with the transaction, the coordinator transits to the  
298 *Preparing* state and begins to execute the two-phase commit protocol by sending the  
299 **wsacid:prepare** message to each participant. If all of the participants indicate that the services  
300 they represent performed no work (i.e., are read only) then the transaction is complete and the  
301 coordinator transits to the *Committed* state.

302 Any failures from a participant or indication that it cannot prepare cause the coordinator to  
303 rollback (move to the *RollingBack* state) and send **wsacid:rollback** messages to all of the  
304 participants. It then transits to the *RolledBack* state.

305

306

**Figure 4, Transaction coordinator two-phase status transition.**

307

Assuming all participants have prepared successfully, the transaction coordinator makes the decision as to whether to commit or rollback and must record sufficient information on stable storage to ensure this decision can be completed in the event of a failure. It is then in the *Prepared* state. When the coordinator starts the second phase of the commit protocol it is in the *Committing* state and ultimately moves to the *Committed* state.

308

309

310

311

If the transaction commits then the protocol-specific termination status within the **wscctx:completed** message will contain the **wsacid:Committed** code. If the transaction rolls back then the code will be **wsacid:RolledBack**. All other errors are communicated using the fault model described earlier.

312

313

314

315

316

### 3.2.2 Coordinator and participant message interactions

317

318

319

320

In this section we shall describe the message exchanged between the coordinator and the participants. Although the text refers to the coordinator soliciting responses from participants, in some cases participants MAY send unsolicited responses to the coordinator; where this is the case it will be explicitly stated.

321

322

323

324

325

326

327

The ACID transaction model supports two styles of participant service implementation: the *singleton* approach, whereby one participant service (end-point) is implicitly associated with only one transaction, and the *factory* approach, whereby a single participant service may manage participants on behalf of many different transactions. Therefore, all operations on the participant service are associated with the current context, i.e., it is propagated to the participants in order to identify which transaction is to be operated on. The unique participant identification is also present on each message.

328

329

330

331

332

The two-phase commit sub-protocol URI is <http://www.webservicestransactions.org/wsd/wstxm/tx-acid/2pc/2003/03> and this is used in the **wscf:addParticipant** message. If the OPTIONAL unique endpoint reference is returned in the **wscf:participantAdded** message then the participant MUST use this for sending coordination signals unless the addressing implementation dictates otherwise.

Comment: Need to update.

333

334

An enlisted Participant Service should expect to receive the following messages (illustrated in **Figure 5**):

Deleted: Figure 5

335

336

337

- prepare: The coordinator is preparing. The participant can respond with a *voteReadOnly*, *voteCommit* or *voteRollback* messages indicating whether or not it is willing to commit. If **voteCommit** is used then optional **Qualifiers** may be sent back to augment the

381

**protocol**. The **wsacid:voteReadOnly** and **wsacid:voteRollback** messages MAY be sent autonomously by the participant, i.e., before any **wsacid:prepare** message is received. However, the participant SHOULD be able to deal with a subsequent **wsacid:prepare** message. If an unreliable transport mechanism is used, then there may be an arbitrary number of these messages. If the participant is a subordinate coordinator and finds that it cannot determine the status of some of its enlisted participants then an error message with the **wsacid:HeuristicHazard** error code will be returned. Alternatively, if a subordinate coordinator finds that some of the participants have committed and some have rolled back then it must return the **wsacid:HeuristicMixed** error message.

Comment: Issue 275

- **rollback**: The coordinator is rolling back. If the participant is receiving this message after a **wsacid:prepare** message, then any error at this point will cause a heuristic outcome. If the participant is a subordinate coordinator and cannot determine how all of its enlisted participants terminated then it must return an error message with the **wsacid:HeuristicHazard** fault code. If the participant is a subordinate coordinator and some of its enlisted participants committed then it must return the **wsacid:HeuristicMixed** fault code. If the participant commits rather than rolls back then it must return the **wsacid:HeuristicCommit** message. Otherwise the participant sends the *rolledback* message. The **wsacid:rolledback** message MAY be sent autonomously by the participant, i.e., before any **wsacid:rollback** message is received. However, the participant SHOULD be able to deal with a subsequent **wsacid:rollback** message. If an unreliable transport mechanism is used, then there may be an arbitrary number of these messages.
- **commit**: The coordinator is top-level and is committing. Any error at this point will cause a heuristic outcome. If the participant is a subordinate coordinator and cannot determine how all of its enlisted participants terminated then it must return an error message with the **wsacid:HeuristicHazard** fault code. If the participant is a subordinate coordinator and some of its enlisted participants committed then it must return the **wsacid:HeuristicMixed** fault code. If the participant rolls back rather than commits then it must return the **wsacid:HeuristicRollback** fault code. Otherwise the participant returns a *committed* message.
- **onePhaseCommit**: If only a single participant is registered with a two-phase coordinator then the coordinator SHOULD optimize the commit stage by not executing the prepare phase. If the participant is a subordinate coordinator and cannot determine how all of its enlisted participants terminated then it must return an error message with the **wsacid:HeuristicHazard** fault code. If the participant is a subordinate coordinator and some of its enlisted participants committed then it must return the **wsacid:HeuristicMixed** fault code. Otherwise the participant returns either the *committed* or *rolledback* message.
- **forgetHeuristic**: The participant made a post-prepare choice that was contrary to the coordinator's outcome. Hence it may have caused a non-atomic (heuristic) outcome. If this happens, the participant *must* remember the decision it took (persistently) until the coordinator tells it via this message that it is safe to forget. Success is indicated by sending the *heuristicForgotten* message. Any other response is assumed to indicate a failure.

Comment: SOAP faults

Figure 5, Coordinator-to-participant message exchanges.

The WSDL portType declarations for the CoordinatorParticipant and twoPCParticipant roles are shown in Figure 6.

**Comment:** Need to change the names.

420 Figure 6, WSDL portType Declarations for Coordinator and 2PCParticipant Roles

### 421 3.3 Pre- and post- two-phase commit processing

422 Most modern transaction processing systems allow the creation of participants that do not take  
423 part in the two-phase commit protocol, but are informed before it begins and after it has  
424 completed. They are called *Synchronizations*, and are typically employed to flush volatile  
425 (cached) state, which may be being used to improve performance of an application, to a  
426 recoverable object or database prior to the transaction committing; once flushed, the data will the  
427 be controlled by a two-phase aware participant.

428 The sub-protocol URI for the synchronization protocol is  
429 <http://www.webservicestransactions.org/wsdl/wstxm/tx-acid/sync/2003/03> and this is used in the  
430 **wscf:addParticipant** invocation.

**Comment:** Needs updating.

431 The message exchanges (ignoring the normal WS-CF coordinator-to-participant message  
432 exchanges, including failures) are illustrated in [Figure 7](#):

**Deleted:** Figure 7

- 433 • beforeCompletion: A Synchronization participant is informed that the coordinator it is  
434 registered with is about to complete the two-phase protocol and in what state, i.e.,  
435 committing or rolling back. Any failure at this stage will cause the coordinator to rollback if  
436 it is not already doing so. Success is indicated by the **wscid:beforeCompleted**  
437 message.
- 438 • afterCompletion: A Synchronization participant is informed that the coordinator it is  
439 registered with has completed the two-phase protocol and in what state, i.e., committed  
440 or rolled back (via the associated **wscid:status**). Any failures at this stage have no  
441 affect on the transaction; an implementation MAY report these failures. Success is  
442 indicated by the **wscid:afterCompleted** message.

**Comment:** Ensure consistency.

443

444 **Figure 7, AT coordinator-to-synchronization message exchanges.**

445 The WSDL portType declarations for the CoordinatorParticipant and Synchronization roles are  
446 shown in [Figure 8](#):

**Deleted:** Figure 8

```

447 <wsdl:portType name="SynchronizationPortType">
448 <wsdl:operation name="beforeCompletion">

```

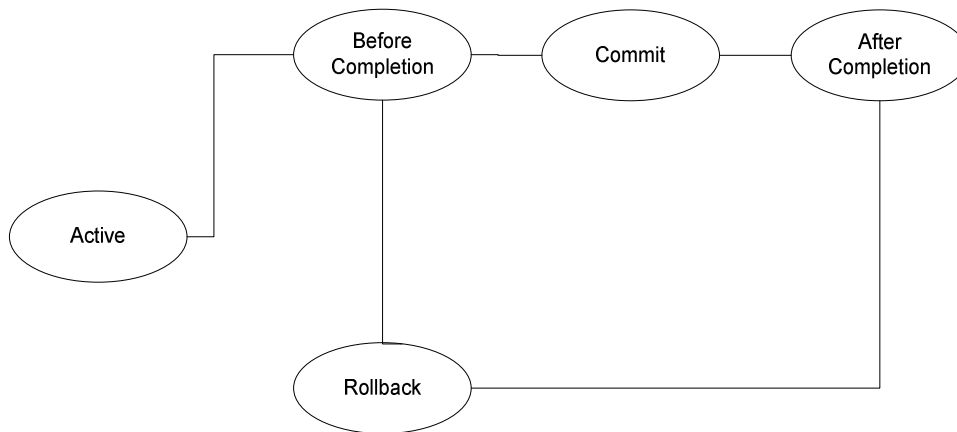

```

449     <wsdl:input message="tns:BeforeCompletionMessage"/>
450   </wsdl:operation>
451   <wsdl:operation name="afterCompletion">
452     <wsdl:input message="tns:AfterCompletionMessage"/>
453   </wsdl:operation>
454 </wsdl:portType>
455 <wsdl:portType name="CoordinatorParticipantPortType">
456   <wsdl:operation name="beforeCompletionParticipantRegistered">
457     <wsdl:input
458 message="tns:BeforeCompletionParticipantRegisteredMessage"/>
459   </wsdl:operation>
460   <wsdl:operation name="afterCompletionParticipantRegistered">
461     <wsdl:input
462 message="tns:AfterCompletionParticipantRegisteredMessage"/>
463   </wsdl:operation>
464 </wsdl:portType>

```

465 *Figure 8, WSDL portType Declarations for Coordinator and 2PCParticipant Roles.*

466 The state transition for the transaction coordinator which has enrolled Synchronizations is shown  
467 in Figure 12. In this scenario we assume the transaction is committing: if it were to rollback, then  
468 only the *AfterCompletion* message will be sent from the coordinator to the Synchronization  
469 participants.

470  
471 **Figure 9, Transaction coordinator Synchronization state transitions.**

472 The coordinator moves into the *BeforeCompletion* state and sends each enrolled Synchronization  
473 the **wsacid:beforeCompletion** message. Any error received by the coordinator from a  
474 Synchronization at this stage will force the transaction to roll back. Assuming no errors occur, the  
475 two-phase commit protocol is executed, as detailed previously. Once the protocol has completed,  
476 the coordinator transits to the *AfterCompletion* status and sends the **wsacid:afterCompletion**  
477 message to all Synchronizations; any errors at this stage do not affect the transaction outcome  
478 and how they are dealt with is implementation dependant.

### 479 3.4 Checked transactions

480 Checked transactions have a number of integrity constraints including:

- 481 • Ensuring that only the transaction originator can commit the transaction.
- 482 • Ensuring that a transaction will not commit until all transactional invocations involved in  
483 the transaction have completed.

484 Some implementations will enforce checked behavior for the transactions they support, to provide  
485 an extra level of transaction integrity. The purpose of the checks is to ensure that all transactional  
486 requests made by the application have completed their processing before the transaction is  
487 committed. A checked Transaction Service guarantees that commit will not succeed unless all  
488 invocations involved in the transaction have completed. Rolling back the transaction does not  
489 require such as check, since all outstanding transactional activities will eventually rollback if they  
490 are not told to commit

491 There are many possible implementations of checked transactions. One provides equivalent  
492 function to that provided by the request/response inter-process communication models defined by  
493 X/Open. It describes the transaction integrity guarantees provided by many existing transaction  
494 systems. In X/Open, completion of the processing of a request means that the service has  
495 completed execution of its invocation and replied to the request. The level of transaction integrity  
496 provided by a Transaction Service implementing the X/Open model of checking provides  
497 equivalent function to that provided by the XATMI and TxRPC interfaces defined by X/Open for  
498 transactional applications.

### 499 3.5 Recovery and interposition

500 Because WS-ACID is a Referencing Specification of WS-CF, interposition is allowed though not  
501 required. Individual participants may be subordinate coordinators to improve performance or to  
502 federate a distributed environment into separate domains (possibly managed by different  
503 organizations or transaction management systems).

504 Each participant or subordinate coordinator is responsible for ensuring that sufficient data is  
505 made durable in order to complete the transaction in the event of failures. *Recovering participants  
506 or coordinators use the recovery mechanisms defined in WS-CF to determine the current status  
507 of a transaction/participant and act accordingly.* Interposition and check pointing of state allow the  
508 system to drive a consistent view of the outcome and recovery actions taken, but allowing always  
509 the possibility that recovery isn't possible and must be logged or flagged for the administrator.

510 Although enterprise transaction systems address the aspects of distributed recovery, in a large  
511 scale environment or in the presence of long term failures, recovery may not be automatic. As  
512 such, manual intervention may be necessary to restore an application's consistency.

### 513 3.6 The context

```
514 <xs:complexType name="ContextType">  
515   <xs:complexContent>  
516     <xs:extension base="wstxm:ContextType"/>  
517   </xs:complexContent>  
518 </xs:complexType>  
519 <xs:element name="context" type="tns:ContextType"/>
```

520 *Figure 10, Transaction Context.*

### 521 3.7 Statuses

522 The following extensions to the **wscxtx:Status** type MAY be returned by participants and the  
523 Context Service to indicate the outcome of executing relevant parts of the protocol; they MAY  
524 also be used to indicate the current status of the transaction:

**Comment:** Place holder as I think Greg has the AI for this under the general issue of asynchronous transactions.

**Comment:** This needs reworking because of WS-Context changes.

**Comment:** Issue – need to add a getStatus to the Participant Service WSDL?

- 525 • RollbackOnly: the status of the endpoint is that it will roll back eventually.
- 526 • RollingBack: the endpoint is in the process of rolling back.
- 527 • RolledBack: the endpoint has rolled back.
- 528 • Committing: the endpoint is in the process of committing. This does not mean that the
- 529 final outcome will be Committed.
- 530 • Committed: the endpoint has committed.
- 531 • HeuristicRollback: all of the participants rolled back when they were asked to commit.
- 532 • HeuristicCommit: all of the participants committed when they were asked to rollback.
- 533 • HeuristicHazard: some of the participants rolled back, some committed and the outcome
- 534 of others is indeterminate.
- 535 • HeuristicMixed: some of the participants rolled back whereas the remainder committed.
- 536 • Preparing: the endpoint is preparing.
- 537 • Prepared: the endpoint has prepared.

538 These are specified in the schema, as per [Figure 11](#).

Deleted: Figure 11

```

539 <xs:simpleType name="StatusType">
540 <xs:restriction base="wstxm:StatusType">
541 <xs:enumeration value="activity.status.tx-acid.ROLLBACK_ONLY"/>
542 <xs:enumeration value="activity.status.tx-acid.ROLLING_BACK"/>
543 <xs:enumeration value="activity.status.tx-acid.ROLLED_BACK"/>
544 <xs:enumeration value="activity.status.tx-acid.COMMITTING"/>
545 <xs:enumeration value="activity.status.tx-acid.COMMITTED"/>
546 <xs:enumeration value="activity.status.tx-
547 acid.HEURISTIC_ROLLBACK"/>
548 <xs:enumeration value="activity.status.tx-acid.HEURISTIC_COMMIT"/>
549 <xs:enumeration value="activity.status.tx-acid.HEURISTIC_HAZARD"/>
550 <xs:enumeration value="activity.status.tx-acid.HEURISTIC_MIXED"/>
551 <xs:enumeration value="activity.status.tx-acid.PREPARING"/>
552 <xs:enumeration value="activity.status.tx-acid.PREPARED"/>
553 </xs:restriction>
554 </xs:simpleType>

```

555 *Figure 11, StatusType.*

Comment: Add the structure information for data within wsctx:complete and wsctx:completed messages.

### 556 3.8 WS-ACID Faults

557 This section defines well-known error codes to be used in conjunction with an underlying fault  
 558 handling mechanism.

#### 559 Heuristic Hazard

560 This fault is sent by a participant or the ContextService in response to **wsctx:complete** to  
 561 indicate that the participant/transaction has terminated in a non-atomic manner. The termination  
 562 status of all participants (committed or rolled back) is not known.

563 The qualified name of the fault code is:

```

564 wsacid:HeuristicHazard

```

#### 565 Heuristic Mixed

566 This fault is sent by a participant or the ContextService in response to **wsctx:complete** to  
 567 indicate that the participant/transaction has terminated in a non-atomic manner. The termination  
 568 status of some participants was to commit whereas others rolled back.

569 The qualified name of the fault code is:

570

wsacid:HeuristicMixed

### 571 **Heuristic Rollback**

572 This fault is sent by a participant or the ContextService in response to **wsctx:complete** to  
573 indicate that the participant/transaction has rolled back. If this is from the transaction, then all of  
574 the participants autonomously rolled back.

575 The qualified name of the fault code is:

576

wsacid:HeuristicRollback

### 577 **Heuristic Commit**

578 This fault is sent by a participant or the ContextService in response to **wsctx:complete** to  
579 indicate that the participant/transaction has committed. If this is from the transaction, then all of  
580 the participants autonomously committed.

581 The qualified name of the fault code is:

582

wsacid:HeuristicCommit

## 583 **3.9 Message exchanges**

584 The WS-CAF protocol family is defined in WSDL, with associated schemas. All the WSDL has a  
585 common pattern of defining paired port-types, such that one port-type is effectively the requestor,  
586 the other the responder for some set of request-response operations.

587 portType for an initiator (“client” for the operation pair) will expose the responses of the  
588 “request/response” as input operations (and should expose the requests as output messages);  
589 the responder (service-side) only exposes the request operations as input operations (and should  
590 expose the responses as output messages).

591 Each “response” is shown on the same line as the “request” that invokes it. Where there are a  
592 number of responses to a “request”, these are shown on successive lines. The initiator portTypes  
593 typically include various fault and error operations.

Initiator (and receiver of response)	Responder	“requests”	responses
<b>CoordinatorParticipant</b>	<b>Synchronization ParticipantService</b>	beforeCompletion	beforeCompleted wsctx:InvalidState wsctx:InvalidContext wsctx:NoPermission wsctx:NoContext
		afterCompletion	afterCompleted wsctx:InvalidState wsctx:InvalidContext wsctx:NoPermission wsctx:NoContext

Initiator (and receiver of response)	Responder	“requests”	responses
<b>CoordinatorParticipant</b>	<b>TwoPhase ParticipantService</b>	prepare	voteReadOnly voteCommit voteRollback HeuristicMixed HeuristicHazard wsctx:InvalidState wsctx:InvalidContext wsctx:NoContext
		commit	committed HeuristicRollback HeuristicMixed HeuristicHazard wsctx:InvalidState wsctx:InvalidContext wsctx:NoPermission wsctx:NoContext
		rollback	rolledback HeuristicCommit HeuristicMixed HeuristicHazard wsctx:InvalidState wsctx:InvalidContext wsctx:NoPermission wsctx:NoContext
		commitOnePhase	committed rolledback HeuristicMixed HeuristicHazard wsctx:InvalidState wsctx:InvalidContext wsctx:NoPermission wsctx:NoContext
		forgetHeuristic	heuristicForgotten wsctx:InvalidState wsctx:InvalidContext wsctx:NoPermission wsctx:NoContext
		getStatus	status wsctx:InvalidState wsctx:InvalidContext wsctx:NoPermission wsctx:NoContext
<b>wsctx:UserContextService</b>	<b>wsctx:ContextService</b>	wsctx:complete (wsacid:Commit) (wsacid:Rollback)	wsctx:completed (wsacid:Committed) (wsacid:RolledBack) wsacid:HeuristicMixed wsacid:HeuristicHazard
