45 **Abstract:**

46 This non-normative specification describes and analyzes the security and privacy properties of
47 SAML.

48 **Status:**

49 This is a **Committee Draft** approved by the Security Services Technical Committee on 14
50 December 2004.

51 Committee members should submit comments and potential errata to the [security-](mailto:security-services@lists.oasis-open.org)
52 [services@lists.oasis-open.org](mailto:security-services@lists.oasis-open.org) list. Others should submit them by filling out the web form located
53 at http://www.oasis-open.org/committees/comments/form.php?wg_abbrev=security. The
54 committee will publish on its web page (<http://www.oasis-open.org/committees/security>) a catalog
55 of any changes made to this document.

56 For information on whether any patents have been disclosed that may be essential to
57 implementing this specification, and any offers of patent licensing terms, please refer to the
58 Intellectual Property Rights web page for the Security Services TC ([http://www.oasis-](http://www.oasis-open.org/committees/security/ipr.php)
59 [open.org/committees/security/ipr.php](http://www.oasis-open.org/committees/security/ipr.php)).

1 Introduction

146

147 This non-normative document describes and analyzes the security and privacy properties of the OASIS
148 Security Assertion Markup Language (SAML) defined in the core SAML specification [SAMLCore] and the
149 SAML bindings [SAMLBind] and profiles [SAMLProf] specifications. The intent in this document is to
150 provide information to architects, implementors, and reviewers of SAML-based systems about the
151 following:

- 152 • The privacy issues to be considered and how SAML architecture addresses these issues
- 153 • The threats, and thus security risks, to which a SAML-based system is subject
- 154 • The security risks the SAML architecture addresses, and how it does so
- 155 • The security risks it does not address
- 156 • Recommendations for countermeasures that mitigate those security risks

157 Terms used in this document are as defined in the SAML glossary [SAMLGloss] unless otherwise noted.

158 The rest of this section describes the background and assumptions underlying the analysis in this
159 document. Section 4 provides a high-level view of security techniques and technologies that should be
160 used with SAML. The following sections analyze the risks associated with the SAML assertions and
161 protocol as well as specific risks associated with SAML bindings and profiles.

2 Privacy

162

163 SAML includes the ability to make statements about the attributes and authorizations of authenticated
164 entities. There are very many common situations in which the information carried in these statements is
165 something that one or more of the parties to a communication would desire to keep accessible to as
166 restricted as possible a set of entities. Statements of medical or financial attributes are simple examples of
167 such cases.

168 Many countries and jurisdictions have laws and regulations regarding privacy and these should be
169 considered when deploying a SAML based system. A more extensive discussion of the legal issues
170 related to privacy and best practices related to privacy may be found in the Liberty Privacy and Security
171 Best Practices document [LibBestPractices].

172 Parties making statements, issuing assertions, conveying assertions, and consuming assertions must be
173 aware of these potential privacy concerns and should attempt to address them in their implementations of
174 SAML-aware systems.

2.1 Ensuring Confidentiality

175

176 Perhaps the most important aspect of ensuring privacy to parties in a SAML-enabled transaction is the
177 ability to carry out the transaction with a guarantee of confidentiality. In other words, can the information in
178 an assertion be conveyed from the issuer to the intended audience, and only the intended audience,
179 without making it accessible to any other parties?

180 It is technically possible to convey information confidentially (a discussion of common methods for
181 providing confidentiality occurs in the Security portion of the document in Section 4.2). All parties to SAML-
182 enabled transactions should analyze each of their steps in the interaction (and any subsequent uses of
183 data obtained from the transactions) to ensure that information that should be kept confidential is actually
184 being kept so.

185 It should also be noted that simply obscuring the contents of assertions may not be adequate protection of
186 privacy. There are many cases where just the availability of the information that a given user (or IP
187 address) was accessing a given service may constitute a breach of privacy (for example, an the
188 information that a user accessed a medical testing facility for an assertion may be enough to breach
189 privacy without knowing the contents of the assertion). Partial solutions to these problems can be provided
190 by various techniques for anonymous interaction, outlined below.

2.2 Notes on Anonymity

191

192 The following sections discuss the concept of anonymity.

2.2.1 Definitions That Relate to Anonymity

193

194 There are no definitions of anonymity that are satisfying for all cases. Many definitions [Anonymity] deal
195 with the simple case of a sender and a message, and discuss “anonymity” in terms of not being able to
196 link a given sender to a sent message, or a message back to a sender.

197 And while that definition is adequate for the “one off” case, it ignores the aggregation of information that is
198 possible over time based on behavior rather than an identifier.

199 Two notions that may be generally useful, and that relate to each other, can help define anonymity.

200 The first notion is to think about anonymity as being “within a set”, as in this comment from “Anonymity,
201 Unobservability, and Pseudonymity” [Anonymity]:

202 *To enable anonymity of a subject, there always has to be an appropriate set of subjects with*
203 *potentially the same attributes....*

204 *...Anonymity is the stronger, the larger the respective anonymity set is and the more evenly*
205 *distributed the sending or receiving, respectively, of the subjects within that set is.*

206 This notion is relevant to SAML because of the use of authorities. Even if a Subject is “anonymous”, that
207 subject is still identifiable as a member of the set of Subjects within the domain of the relevant authority.

208 In the case where aggregating attributes of the user are provided, the set can become much smaller – for
209 example, if the user is “anonymous” but has the attribute of “student in Course 6@mit.edu”. Certainly, the
210 number of Course 6 students is less than the number of MIT-affiliated persons which is less than the
211 number of users everywhere.

212 Why does this matter? Non-anonymity leads to the ability of an adversary to harm, as expressed in
213 Dingedine, Freedman, and Molnar’s Freehaven document [FreeHaven]:

214 *Both anonymity and pseudonymity protect the privacy of the user’s location and true name.*
215 *Location refers to the actual physical connection to the system. The term “true name” was*
216 *introduced by Vinge and popularized by May to refer to the legal identity of an individual.*
217 *Knowing someone’s true name or location allows you to hurt him or her.*

218 This leads to a unification of the notion of anonymity within a set and ability to harm, from the same source
219 [FreeHaven]:

220 *We might say that a system is partially anonymous if an adversary can only narrow down a*
221 *search for a user to one of a ‘set of suspects.’ If the set is large enough, then it is impractical*
222 *for an adversary to act as if any single suspect were guilty. On the other hand, when the set*
223 *of suspects is small, mere suspicion may cause an adversary to take action against all of*
224 *them.*

225 SAML-enabled systems are limited to "partial anonymity" at best because of the use of authorities. An
226 entity about whom an assertion is made is already identifiable as one of the pool of entities in a
227 relationship with the issuing authority.

228 The limitations on anonymity can be much worse than simple authority association, depending on how
229 identifiers are employed, as reuse of pseudonymous identifiers allows accretion of potentially identifying
230 information (see Section 2.2.2). Additionally, users of SAML-enabled systems can also make the breach
231 of anonymity worse by their actions (see Section 2.2.3).

232 **2.2.2 Pseudonymity and Anonymity**

233 Apart from legal identity, any identifier for a Subject can be considered a pseudonym. And even notions
234 like “holder of key” can be considered as serving as the equivalent of a pseudonym in linking an action (or
235 set of actions) to a Subject. Even a description such as “the user that just requested access to object XYZ
236 at time 23:34” can serve as an equivalent of a pseudonym.

237 Thus, that with respect to “ability to harm,” it makes no difference whether the user is described with an
238 identifier or described by behavior (for example, use of a key or performance of an action).

239 What does make a difference is how often the particular equivalent of a pseudonym is used.

240 [Anonymity] gives a taxonomy of pseudonyms starting from personal pseudonyms (like nicknames) that
241 are used all the time, through various types of role pseudonyms (such as Secretary of Defense), on to
242 “one-time-use” pseudonyms.

243 Only one-time-use pseudonyms can give you anonymity (within SAML, consider this as "anonymity within
244 a set").

245 The more often you use a given pseudonym, the more you reduce your anonymity and the more likely it is
246 that you can be harmed. In other words, reuse of a pseudonym allows additional potentially identifying
247 information to be associated with the pseudonym. Over time, this will lead to an accretion that can
248 uniquely identify the identity associated with a pseudonym.

249 **2.2.3 Behavior and Anonymity**

250 As Joe Klein can attest, anonymity isn’t all it is cracked up to be.

251 Klein is the "Anonymous" who authored Primary Colors. Despite his denials he was unmasked as the
252 author by Don Foster, a Vassar professor who did a forensic analysis of the text of Primary Colors. Foster
253 compared that text with texts from a list of suspects that he devised based on their knowledge bases and
254 writing proclivities.

255 It was Klein's idiosyncratic usages that did him in (though apparently all authors have them).
256 The relevant point for SAML is that an "anonymous" user (even one that is never named) can be identified
257 enough to be harmed by repeated unusual behavior. Here are some examples:
258 • A user who each Tuesday at 21:00 access a database that correlates finger lengths and life span
259 starts to be non-anonymous. Depending on that user's other behavior, she or he may become
260 "traceable" [Pooling] in that other "identifying" information may be able to be collected.
261 • A user who routinely buys a usual set of products from a networked vending machine certainly
262 opens themselves to harm (by virtue of booby-trapping the products).

263 **2.2.4 Implications for Privacy**

264 Origin site authorities (such as authentication authorities and attribute authorities) can provide a degree of
265 "partial anonymity" by employing one-time-use identifiers or keys (for the "holder of key" case).

266 This anonymity is "partial" at best because the Subject is necessarily confined to the set of Subjects in a
267 relationship with the Authority.

268 This set may be further reduced (thus further reducing anonymity) when aggregating attributes are used
269 that further subset the user community at the origin site.

270 Users who truly care about anonymity must take care to disguise or avoid unusual patterns of behavior
271 that could serve to "de-anonymize" them over time.

272 3 Security

273 The following sections discuss security considerations.

274 3.1 Background

275 Communication between computer-based systems is subject to a variety of threats, and these threats
276 carry some level of associated risk. The nature of the risk depends on a host of factors, including the
277 nature of the communications, the nature of the communicating systems, the communication mediums,
278 the communication environment, the end-system environments, and so on. Section 3 of the IETF
279 guidelines on writing security considerations for RFCs [Rescorla-Sec] provides an overview of threats
280 inherent in the Internet (and, by implication, intranets).

281 SAML is intended to aid deployers in establishing security contexts for application-level computer-based
282 communications within or between security domains. In this role, SAML transfers authentication data,
283 supporting end systems' ability to protect against unauthorized usage. Communications security is directly
284 applicable to the design of SAML. Systems security is of interest mostly in the context of SAML's threat
285 models. Section 2 of the IETF guidelines gives an overview of communications security and systems
286 security.

287 3.2 Scope

288 Some areas that impact broadly on the overall security of a system that uses SAML are explicitly outside
289 the scope of SAML. While this document does not address these areas, they should always be
290 considered when reviewing the security of a system. In particular, these issues are important, but currently
291 beyond the scope of SAML:

- 292 • Initial authentication: SAML allows statements to be made about acts of authentication that have
293 occurred, but includes no requirements or specifications for these acts of authentication.
294 Consumers of authentication assertions should be wary of blindly trusting these assertions
295 unless and until they know the basis on which they were made. Confidence in the assertions
296 must never exceed the confidence that the asserting party has correctly arrived at the
297 conclusions asserted.
- 298 • Trust Model: In many cases, the security of a SAML conversation will depend on the underlying
299 trust model, which is typically based on a key management infrastructure (for example, PKI or
300 secret key). For example, SOAP messages secured by means of XML Signature [XMLSig] are
301 secured only insofar as the keys used in the exchange can be trusted. Undetected compromised
302 keys or revoked certificates, for example, could allow a breach of security. Even failure to require
303 a certificate opens the door for impersonation attacks. PKI setup is not trivial and must be
304 implemented correctly in order for layers built on top of it (such as parts of SAML) to be secure.
- 305 • Suitable implementations of security protocols is necessary to maintain the security of a system,
306 including secure random or pseudo-random number generation and secure key storage.

307 3.3 SAML Threat Model

308 The general Internet threat model described in the IETF guidelines for security considerations [Rescorla-
309 Sec] is the basis for the SAML threat model. We assume here that the two or more endpoints of a SAML
310 transaction are uncompromised, but that the attacker has complete control over the communications
311 channel.

312 Additionally, due to the nature of SAML as a multi-party authentication and authorization statement
313 protocol, cases must be considered where one or more of the parties in a legitimate SAML transaction—
314 who operate legitimately within their role for that transaction—attempt to use information gained from a
315 previous transaction maliciously in a subsequent transaction.

316 The following scenarios describe possible attacks:

- 317 • Collusion: The secret cooperation between two or more system entities to launch an attack, for
318 example:
- 319 Collusion between Principal and service provider
320 Collusion between Principal and identity provider
321 Collusion between identity provider and service provider
322 Collusion among two or more Principals
323 Collusion between two or more service providers
324 Collusion between two or more identity providers
- 325 • Denial-of-Service Attacks: The prevention of authorized access to a system resource or the
326 delaying of system operations and functions.
- 327 • Man-in-the-Middle Attacks: A form of active wiretapping attack in which the attacker intercepts
328 and selectively modifies communicated data to masquerade as one or more of the entities
329 involved in a communication association.
- 330 • Replay Attacks: An attack in which a valid data transmission is maliciously or fraudulently
331 repeated, either by the originator or by an adversary who intercepts the data and retransmits it,
332 possibly as part of a masquerade attack.
- 333 • Session Hijacking: A form of active wiretapping in which the attacker seizes control of a
334 previously established communication association.

335 In all cases, the local mechanisms that systems will use to decide whether or not to generate assertions
336 are out of scope. Thus, threats arising from the details of the original login at an authentication authority,
337 for example, are out of scope as well. If an authority issues a false assertion, then the threats arising from
338 the consumption of that assertion by downstream systems are explicitly out of scope.

339 The direct consequence of such a scoping is that the security of a system based on assertions as inputs is
340 only as good as the security of the system used to generate those assertions, and of the correctness of
341 the data and processing on which the generated assertions are based. When determining what issuers to
342 trust, particularly in cases where the assertions will be used as inputs to authentication or authorization
343 decisions, the risk of security compromises arising from the consumption of false but validly issued
344 assertions is a large one. Trust policies between asserting and relying parties should always be written to
345 include significant consideration of liability and implementations should provide an appropriate audit trail.

346 4 Security Techniques

347 The following sections describe security techniques and various stock technologies available for their
348 implementation in SAML deployments.

349 4.1 Authentication

350 Authentication here means the ability of a party to a transaction to determine the identity of the other party
351 in the transaction. This authentication may be in one direction or it may be bilateral.

352 4.1.1 Active Session

353 Non-persistent authentication is provided by the communications channel used to transport a SAML
354 message. This authentication may be unilateral—from the session initiator to the receiver—or bilateral.
355 The specific method will be determined by the communications protocol used. For instance, the use of a
356 secure network protocol, such as TLS [RFC2246] or the IP Security Protocol [IPsec], provides the SAML
357 message sender with the ability to authenticate the destination for the TCP/IP environment.

358 4.1.2 Message-Level

359 XML Signature [XMLSig] and the OASIS Web Services Security specifications [WSS] provide methods of
360 creating a persistent “authentication” that is tightly coupled to a document. This method does not
361 independently guarantee that the sender of the message is in fact that signer (and indeed, in many cases
362 where intermediaries are involved, this is explicitly not the case).
363 Any method that allows the persistent confirmation of the involvement of a uniquely resolvable entity with a
364 given subset of an XML message is sufficient to meet this requirement.

365 4.2 Confidentiality

366 Confidentiality means that the contents of a message can be read only by the desired recipients and not
367 anyone else who encounters the message.

368 4.2.1 In Transit

369 Use of a secure network protocol such as TLS [RFC2246] or the IP Security Protocol [IPsec] provides
370 transient confidentiality of a message as it is transferred between two nodes.

371 4.2.2 Message-Level

372 XML Encryption [XMLEnc] provides for the selective encryption of XML documents. This encryption
373 method provides persistent, selective confidentiality of elements within an XML message.

374 4.3 Data Integrity

375 Data integrity is the ability to confirm that a given message as received is unaltered from the version of the
376 message that was sent.

377 4.3.1 In Transit

378 Use of a secure network protocol such as TLS [RFC2246] or the IP Security Protocol [IPsec] may be
379 configured to provide integrity protection for the packets transmitted via the network connection.

380 4.3.2 Message-Level

381 XML Signature [XMLSig] provides a method of creating a persistent guarantee of the unaltered nature of a

382 message that is tightly coupled to that message.
383 Any method that allows the persistent confirmation of the unaltered nature of a given subset of an XML
384 message is sufficient to meet this requirement.

385 **4.4 Notes on Key Management**

386 Many points in this document will refer to the ability of systems to provide authentication, data integrity,
387 and confidentiality via various schemes involving digital signature and encryption. For all these schemes
388 the security provided by the scheme is limited based on the key management systems that are in place.
389 Some specific limitations are detailed below.

390 **4.4.1 Access to the Key**

391 It is assumed that, if key-based systems are going to be used for authentication, data integrity, and non-
392 repudiation, security is in place to guarantee that access to a private or secret key representing a principal
393 is not available to inappropriate parties. For example, a digital signature created with Bob's private key is
394 only proof of Bob's involvement to the extent that Bob is the only one with access to the key.

395 In general, access to keys should be kept to the minimum set of entities possible (particularly important for
396 corporate or organizational keys) and should be protected with passphrases and other means. Standard
397 security precautions (don't write down the passphrase, when you're away from a computer don't leave a
398 window with the key accessed open, and so on) apply.

399 **4.4.2 Binding of Identity to Key**

400 For a key-based system to be used for authentication there must be some trusted binding of identity to
401 key. Verifying a digital signature on a document can determine if the document is unaltered since it was
402 signed, and that it was actually signed by a given key. However, this does not confirm that the key used is
403 actually the key of a specific individual appropriate for the time and purpose. Verifying the binding of a key
404 to a party requires additional validation.

405 This key-to-individual binding must be established. Common solutions include local directories that store
406 both identifiers and key—which is simple to understand but difficult to maintain—or the use of certificates.
407 Using certificates can provide a scalable means to associate a key with an identity, but requires
408 mechanisms to manage the certificate lifecycle and changes to the status of the binding (e.g. An
409 employee leaves and no longer has a corporate identity). One common approach is to use a Public Key
410 Infrastructure (PKI).

411 In this case a set of trusted root Certifying Authorities (CAs) are identified for each consumer of signatures
412 —answering the question “Whom do I trust to make statements of identity-to-key binding?” Verification of
413 a signature then becomes a process of first verifying the signature (to determine that the signature was
414 done by the key in question and that the message has not changed) and then validating the certificate
415 chain (to determine that the key is bound to the right identity) and validating that the binding is still
416 appropriate. Validating the binding requires steps to be taken to ensure that the binding is currently valid
417 —a certificate typically has a “lifetime” built into it, but if a key is compromised during the life of the
418 certificate then the key-to-identity binding contained in the certificate becomes invalid while the certificate
419 is still valid on its face. Also, certificates often depend on associations that may end before their lifetime
420 expires (for example, certificates that should become invalid when someone changes employers, etc.)
421 Different mechanisms may be used to validate key and certificate validity, such as Certificate Revocation
422 Lists (CRLs), the Online Certificate Status Protocol [OCSP], or the XML Key Management Specification
423 (XKMS) [XKMS], but these mechanisms are out of scope of the SSTC work.

424 A proper key management system is thus quite strong but very complex. Verifying a signature ends up
425 being a process of verifying the document-to-key binding, then verifying the key-to-identity binding, as well
426 as the current validity of the key and certificate.

427 **4.5 SSL/TLS Cipher Suites**

428 The use of HTTP over SSL 3.0 or TLS 1.0 [RFC2246], or use of URLs with the HTTPS URL scheme, is
429 strongly recommended at many places in this document.

430 Unless otherwise specified, in any SAML binding's use of SSL 3.0 [SSL3] or TLS 1.0 [RFC2246], servers
431 MUST authenticate to clients using a X.509 v3 certificate. The client MUST establish server identity based
432 on contents of the certificate (typically through examination of the certificate's subject DN field).

433 SSL/TLS can be configured to use many different cipher suites, not all of which are adequate to provide
434 "best practices" security. The following sections provide a brief description of cipher suites and
435 recommendations for cipher suite selection.

436 4.5.1 SSL/TLS Cipher Suites

437 **Note:** While references to the US Export restrictions are now obsolete, the constants
438 naming the cipher suites have not changed. Thus,
439 SSL_DHE_DSS_EPORT_WITH_DES40_CBC_SHA is still a valid cipher suite identifier,
440 and the explanation of the historical reasons for the inclusion of "EXPORT" has been left
441 in place in the following summary.

442 A cipher suite combines four kinds of security features, and is given a name in the SSL protocol
443 specification. Before data flows over a SSL connection, both ends attempt to negotiate a cipher suite. This
444 lets them establish an appropriate quality of protection for their communications, within the constraints of
445 the particular mechanism combinations which are available. The features associated with a cipher suite
446 are:

- 447 • The protocol, SSL or TLS.
- 448 • The type of key exchange algorithm used. SSL defines many; the ones that provide server
449 authentication are the most important ones, but anonymous key exchange is supported. (Note
450 that anonymous key exchange algorithms are subject to "man in the middle" attacks, and are **not**
451 **recommended** in the SAML context.) The "RSA" authenticated key exchange algorithm is
452 currently the most interoperable algorithm. Another important key exchange algorithm is the
453 authenticated Diffie-Hellman "DHE_DSS" key exchange, which has no patent-related
454 implementation constraints.¹
- 455 • Whether the key exchange algorithm is freely exportable from the United States of America.
456 Exportable algorithms must use short (512-bit) public keys for key exchange and short (40-bit)
457 symmetric keys for encryption. Keys of these lengths have been successfully attacked, and their
458 use is not recommended.
- 459 • The encryption algorithm used. The fastest option is the RC4 stream cipher; DES and variants
460 (DES40, 3DES-EDE) as well as AES are also supported in "cipher block chaining" (CBC) mode.
461 Other modes are also supported, refer to the TLS documentation [RFC2246].
- 462 • Null encryption is also an option in some cipher suites. Note that null encryption performs **no**
463 encryption; in such cases SSL/TLS is used only to authenticate and provide integrity protection.
464 Cipher suites with null encryption do not provide confidentiality, and **must not be used** in cases
465 where confidentiality is a requirement and is not obtained by means other than SSL/TLS.
- 466 • The digest algorithm used for the Message Authentication Code. The recommended choice is
467 SHA1.
- 468 • For example, the cipher suite named SSL_DHE_DSS_EXPORT_WITH_DES40_CBC_SHA
469 uses SSL, uses an authenticated Diffie-Hellman key exchange (DHE_DSS), is export grade
470 (EXPORT), uses an exportable variant of the DES cipher (DES40_CBC), and uses the SHA1
471 digest algorithm in its MAC (SHA).

472 A given implementation of SSL will support a particular set of cipher suites, and some subset of those will
473 be enabled by default. Applications have a limited degree of control over the cipher suites that are used on
474 their connections; they can enable or disable any of the supported cipher suites, but cannot change the
475 cipher suites that are available.

1 ¹ The RSA algorithm patent has expired; hence this issue is mostly historical.

476 **4.5.2 SSL/TLS Recommendations**

477 SSL 2.0 must not be used due to known security weaknesses. TLS is preferred, SSL 3.0 may also be
478 used.

479 The SAML 2.0 Bindings specification outlines which cipher suites are required and recommended, making
480 normative statements. This section repeats this information for completeness, but that specification is
481 considered normative in case of inconsistency.

482 TLS-capable implementations MUST implement the TLS_RSA_WITH_3DES_EDE_CBC_SHA cipher
483 suite and MAY implement the TLS_RSA_WITH_AES_128_CBC_SHA cipher suite.

484 FIPS [FIPS] TLS-capable implementations MUST implement the corresponding
485 TLS_RSA_FIPS_WITH_3DES_EDE_CBC_SHA cipher suite and MAY implement the corresponding
486 TLS_RSA_FIPS_AES_128_CBC_SHA cipher suite [FIPS].

487 SSL-capable implementations MUST implement the SSL_RSA_WITH_3DES_EDE_CBC_SHA cipher
488 suite.

489 FIPS [FIPS] SSL-capable implementations MUST implement the FIPS ciphersuite corresponding to the
490 SSL SSL_RSA_WITH_3DES_EDE_CBC_SHA cipher suite [FIPS].

491 However, the IETF is moving rapidly towards mandating the use of AES, which has both speed and
492 strength advantages. Forward-looking systems would be wise as well to implement support for the AES
493 cipher suites, such as:

- 494 • TLS_RSA_WITH_AES_128_CBC_SHA

5 General SAML Security Considerations

495

496 The following sections analyze the security risks in using and implementing SAML and describe
497 countermeasures to mitigate the risks.

5.1 SAML Assertions

498

499 At the level of the SAML assertion itself, there is little to be said about security concerns—most concerns
500 arise during communications in the request/response protocol, or during the attempt to use SAML by
501 means of one of the bindings. The consumer is, of course, always expected to honor the validity interval of
502 the assertion and any <OneTimeUse> elements that are present in the assertion.

503 However, one issue at the assertion level bears analysis: an assertion, once issued, is out of the control of
504 the issuer. This fact has a number of ramifications. For example, the issuer has no control over how long
505 the assertion will be persisted in the systems of the consumer; nor does the issuer have control over the
506 parties with whom the consumer will share the assertion information. These concerns are over and above
507 concerns about a malicious attacker who can see the contents of assertions that pass over the wire
508 unencrypted (or insufficiently encrypted).

509 While efforts have been made to address many of these issues within the SAML specification, nothing
510 contained in the specification will erase the requirement for careful consideration of what to put in an
511 assertion. At all times, issuers should consider the possible consequences if the information in the
512 assertion is stored on a remote site, where it can be directly misused, or exposed to potential hackers, or
513 possibly stored for more creatively fraudulent uses. Issuers should also consider the possibility that the
514 information in the assertion could be shared with other parties, or even made public, either intentionally or
515 inadvertently.

5.2 SAML Protocol

516

517 The following sections describe security considerations for the SAML request-response protocol itself,
518 apart from any threats arising from use of a particular protocol binding.

5.2.1 Denial of Service

519

520 The SAML protocol is susceptible to a denial of service (DOS) attack. Handling a SAML request is
521 potentially a very expensive operation, including parsing the request message (typically involving
522 construction of a DOM tree), database/assertion store lookup (potentially on an unindexed key),
523 construction of a response message, and potentially one or more digital signature operations. Thus, the
524 effort required by an attacker generating requests is much lower than the effort needed to handle those
525 requests.

5.2.1.1 Requiring Client Authentication at a Lower Level

526

527 Requiring clients to authenticate at some level below the SAML protocol level (for example, using the
528 SOAP over HTTP binding, with HTTP over TLS/SSL, and with a requirement for client-side certificates
529 that have a trusted Certificate Authority at their root) will provide traceability in the case of a DOS attack.

530 If the authentication is used only to provide traceability, then this does not in itself prevent the attack from
531 occurring, but does function as a deterrent.

532 If the authentication is coupled with some access control system, then DOS attacks from non-insiders is
533 effectively blocked. (Note that it is possible that overloading the client-authentication scheme could still
534 function as a denial-of-service attack on the SAML service, but that this attack needs to be dealt with in
535 the context of the client authentication scheme chosen.)

536 Whatever system of client authentication is used, it should provide the ability to resolve a unique originator
537 for each request, and should not be subject to forgery. (For example, in the traceability-only case, logging
538 the IP address is insufficient since this information can easily be spoofed.)

539 **5.2.1.2 Requiring Signed Requests**

540 In addition to the benefits gained from client authentication discussed in Section 5.2.1.1, requiring a
541 signed request also lessens the order of the asymmetry between the work done by requester and
542 responder. The additional work required of the responder to verify the signature is a relatively small
543 percentage of the total work required of the responder, while the process of calculating the digital
544 signature represents a relatively large amount of work for the requester. Narrowing this asymmetry
545 decreases the risk associated with a DOS attack.

546 Note, however, that an attacker can theoretically capture a signed message and then replay it continually,
547 getting around this requirement. This situation can be avoided by requiring the use of the XML Signature
548 element `<ds:SignatureProperties>` containing a timestamp; the timestamp can then be used to
549 determine if the signature is recent. In this case, the narrower the window of time after issue that a
550 signature is treated as valid, the higher security you have against replay denial of service attacks.

551 **5.2.1.3 Restricting Access to the Interaction URL**

552 Limiting the ability to issue a request to a SAML service at a very low level to a set of known parties
553 drastically reduces the risk of a DOS attack. In this case, only attacks originating from within the finite set
554 of known parties are possible, greatly decreasing exposure both to potentially malicious clients and to
555 DOS attacks using compromised machines as zombies.

556 There are many possible methods of limiting access, such as placing the SAML responder inside a
557 secured intranet and implementing access rules at the router level.

6 SAML Bindings Security Considerations

558

559 The security considerations in the design of the SAML request-response protocol depend to a large extent
560 on the particular protocol binding (as defined in the SAML bindings specification [SAMLBind]) that is used.
561 The bindings sanctioned by the OASIS Security Services Technical Committee are the SOAP binding,
562 Reverse SOAP Binding (PAOS), HTTP Redirect binding, HTTP Redirect/POST binding and HTTP Artifact
563 binding and SAML URI bindings.

6.1 SAML SOAP Binding

564

565 Since the SAML SOAP binding requires no authentication and has no requirements for either in-transit
566 confidentiality or message integrity, it is open to a wide variety of common attacks, which are detailed in
567 the following sections. General considerations are discussed separately from considerations related to the
568 SOAP-over-HTTP case.

6.1.1 Eavesdropping

569

570 **Threat:** Since there is no in-transit confidentiality requirement, it is possible that an eavesdropping party
571 could acquire both the SOAP message containing a request and the SOAP message containing the
572 corresponding response. This acquisition exposes both the nature of the request and the details of the
573 response, possibly including one or more assertions.

574 Exposure of the details of the request will in some cases weaken the security of the requesting party by
575 revealing details of what kinds of assertions it requires, or from whom those assertions are requested. For
576 example, if an eavesdropper can determine that site X is frequently requesting authentication assertions
577 with a given confirmation method from site Y, he may be able to use this information to aid in the
578 compromise of site X.

579 Similarly, eavesdropping on a series of authorization queries could create a “map” of resources that are
580 under the control of a given authorization authority.

581 Additionally, in some cases exposure of the request itself could constitute a violation of privacy. For
582 example, eavesdropping on a query and its response may expose that a given user is active on the
583 querying site, which could be information that should not be divulged in cases such as medical information
584 sites, political sites, and so on. Also the details of any assertions carried in the response may be
585 information that should be kept confidential. This is particularly true for responses containing attribute
586 assertions; if these attributes represent information that should not be available to entities not party to the
587 transaction (credit ratings, medical attributes, and so on), then the risk from eavesdropping is high.

588 **Countermeasures:** In cases where any of these risks is a concern, the countermeasure for
589 eavesdropping attacks is to provide some form of in-transit message confidentiality. For SOAP messages,
590 this confidentiality can be enforced either at the SOAP level or at the SOAP transport level (or some level
591 below it).

592 Adding in-transit confidentiality at the SOAP level means constructing the SOAP message such that,
593 regardless of SOAP transport, no one but the intended party will be able to access the message. The
594 general solution to this problem is likely to be XML Encryption [XMLEnc]. This specification allows
595 encryption of the SOAP message itself, which eliminates the risk of eavesdropping unless the key used in
596 the encryption has been compromised. Alternatively, deployers can depend on the SOAP transport layer,
597 or a layer beneath it, to provide in-transit confidentiality.

598 The details of how to provide this confidentiality depend on the specific SOAP transport chosen. Using
599 HTTP over TLS/SSL (described further in Section 6.1.7) is one method. Other transports will necessitate
600 other in-transit confidentiality techniques; for example, an SMTP transport might use S/MIME.

601 In some cases, a layer beneath the SOAP transport might provide the required in-transit confidentiality.
602 For example, if the request-response interaction is carried out over an IPsec tunnel, then adequate in-
603 transit confidentiality may be provided by the tunnel itself.

604 6.1.2 Replay

605 **Threat:** There is little vulnerability to replay attacks at the level of the SOAP binding. Replay is more of an
606 issue in the various profiles. The primary concern about replay at the SOAP binding level is the potential
607 for use of replay as a denial-of-service attack method.

608 **Countermeasures:** In general, the best way to prevent replay attacks is to prevent the message capture
609 in the first place. Some of the transport-level schemes used to provide in-transit confidentiality will
610 accomplish this goal. For example, if the SAML request-response conversation occurs over SOAP on
611 HTTP/TLS, third parties are prevented from capturing the messages.

612 Note that since the potential replayer does not need to understand the message to replay it, schemes
613 such as XML Encryption do not provide protection against replay. If an attacker can capture a SAML
614 request that has been signed by the requester and encrypted to the responder, then the attacker can
615 replay that request at any time without needing to be able to undo the encryption. The SAML request
616 includes information about the issue time of the request, allowing a determination about whether replay is
617 occurring. Alternatively, the unique key of the request (its ID) can be used to determine if this is a replay
618 request or not.

619 Additional threats from the replay attack include cases where a “charge per request” model is in place.
620 Replay could be used to run up large charges on a given account.

621 Similarly, models where a client is allocated (or purchases) a fixed number of interactions with a system,
622 the replay attack could exhaust these uses unless the issuer is careful to keep track of the unique key of
623 each request.

624 6.1.3 Message Insertion

625 **Threat:** A fabricated request or response is inserted into the message stream. A false response such as
626 a spurious “yes” reply to an authorization decision query or the return of false attribute information in
627 response to an attribute query may result in inappropriate receiver action.

628 **Countermeasures:** The ability to insert a request is not a threat at the SOAP binding level. The threat of
629 inserting a false response can be a denial of service attack, for example returning SOAP Faults for
630 responses, but this attack would become quickly obvious. The more subtle attack of returning fabricated
631 responses is addressed in the SAML protocol, appropriate since according to the SOAP Binding definition
632 each SOAP response must contain a single SAML protocol response unless it contains a fault. The SAML
633 Protocol addresses this with two mechanisms, correlation of responses to requests using the required
634 InResponseTo attribute, making an attack harder since requests must be intercepted to generate
635 responses, and through the support origin authentication, either via signed SAML responses or through a
636 secured transport connection such as SSL/TLS.

637 6.1.4 Message Deletion

638 **Threat:** The message deletion attack would either prevent a request from reaching a responder, or would
639 prevent the response from reaching the requester.

640 **Countermeasures:** In either case, the SOAP binding does not address this threat. In general, correlation
641 of request and response messages may deter such an attack, for example use of the InResponseTo
642 attribute in the SAMLResponseType.

643 6.1.5 Message Modification

644 **Threat:** Message modification is a threat to the SOAP binding in both directions.

645 Modification of the request to alter the details of the request can result in significantly different results
646 being returned, which in turn can be used by a clever attacker to compromise systems depending on the
647 assertions returned. For example, altering the list of requested attributes in the <Attribute> elements
648 could produce results leading to compromise or rejection of the request by the responder.

649 Modification of the request to alter the apparent issuer of the request could result in denial of service or
650 incorrect routing of the response. This alteration would need to occur below the SAML level and is thus
651 out of scope.

652 Modification of the response to alter the details of the assertions therein could result in vast degrees of
653 compromise. The simple examples of altering details of an authentication or an authorization decision
654 could lead to very serious security breaches.

655 **Countermeasures:** In order to address these potential threats, a system that guarantees in-transit
656 message integrity must be used. The SAML protocol and the SOAP binding neither require nor forbid the
657 deployment of systems that guarantee in-transit message integrity, but due to this large threat, it is **highly**
658 **recommended** that such a system be used. At the SOAP binding level, this can be accomplished by
659 digitally signing requests and responses with a system such as XML Signature [XMLSig]. The SAML
660 specification allows for such signatures; see the SAML assertion and protocol specification [SAMLCore]
661 for further information.

662 If messages are digitally signed (with a sensible key management infrastructure, see Section 4.4) then the
663 recipient has a guarantee that the message has not been altered in transit, unless the key used has been
664 compromised.

665 The goal of in-transit message integrity can also be accomplished at a lower level by using a SOAP
666 transport that provides the property of guaranteed integrity, or is based on a protocol that provides such a
667 property. SOAP over HTTP over TLS/SSL is a transport that would provide such a guarantee.

668 Encryption alone does not provide this protection, as even if the intercepted message could not be altered
669 per se, it could be replaced with a newly created one.

670 6.1.6 Man-in-the-Middle

671 **Threat:** The SOAP binding is susceptible to man-in-the-middle (MITM) attacks. In order to prevent
672 malicious entities from operating as a man in the middle (with all the perils discussed in both the
673 eavesdropping and message modification sections), some sort of bilateral authentication is required.

674 **Countermeasures:** A bilateral authentication system would allow both parties to determine that what they
675 are seeing in a conversation actually came from the other party to the conversation.

676 At the SOAP binding level, this goal could also be accomplished by digitally signing both requests and
677 responses (with all the caveats discussed in Section 6.1.5 above). This method does not prevent an
678 eavesdropper from sitting in the middle and forwarding both ways, but he is prevented from altering the
679 conversation in any way without being detected.

680 Since many applications of SOAP do not use sessions, this sort of authentication of author (as opposed to
681 authentication of sender) may need to be combined with information from the transport layer to confirm
682 that the sender and the author are the same party in order to prevent a weaker form of "MITM as
683 eavesdropper".

684 Another implementation would depend on a SOAP transport that provides, or is implemented on a lower
685 layer that provides, bilateral authentication. The example of this is again SOAP over HTTP over TLS/SSL
686 with both server- and client-side certificates required.

687 Additionally, the validity interval of the assertions returned functions as an adjustment on the degree of
688 risk from MITM attacks. The shorter the valid window of the assertion, the less damage can be done if it is
689 intercepted.

690 6.1.7 Use of SOAP over HTTP

691 Since the SOAP binding requires that conformant applications support HTTP over TLS/SSL with a number
692 of different bilateral authentication methods such as Basic over server-side SSL and certificate-backed
693 authentication over server-side SSL, these methods are always available to mitigate threats in cases
694 where other lower-level systems are not available and the above listed attacks are considered significant
695 threats.

696 This does not mean that use of HTTP over TLS with some form of bilateral authentication is mandatory. If
697 an acceptable level of protection from the various risks can be arrived at through other means (for
698 example, by an IPsec tunnel), full TLS with certificates is not required. However, in the majority of cases
699 for SOAP over HTTP, using HTTP over TLS with bilateral authentication will be the appropriate choice.

700 The HTTP Authentication RFC [RFC2617] describes possible attacks in the HTTP environment when
701 basic or message-digest authentication schemes are used.

702 Note, however, that the use of transport-level security (such as the SSL or TLS protocols under HTTP)
703 only provides confidentiality and/or integrity and/or authentication for “one hop”. For models where there
704 may be intermediaries, or the assertions in question need to live over more than one hop, the use of
705 HTTP with TLS/SSL does not provide adequate security.

706 **6.2 Reverse SOAP (PAOS) Binding**

707 **6.2.1 Denial of Service**

708 **Threat:** Remove HTTP accept header field and/or the PAOS HTTP header field causing HTTP responder
709 to ignore PAOS processing possibility.

710 **Countermeasures:** Integrity protect the HTTP message, using SSL/TLS integrity protection or other
711 adequate transport layer security mechanism.

712 **6.3 HTTP Redirect binding**

713 **6.3.1 Denial of Service**

714 **Threat:** Malicious redirects into identity or service provider targets

715 Description: A spurious entity could issue a redirect to a user agent so that the user agent would access a
716 resource that disrupts single sign-on. For example, an attacker could redirect the user agent to a logout
717 resource of a service provider causing the Principal to be logged out of all existing authentication
718 sessions.

719 **Countermeasures:** Access to resources that produce side effects could be specified with a transient
720 qualifier that must correspond to the current authentication session. Alternatively, a confirmation dialog
721 could be interposed that relies on a transient qualifier with similar semantics.

722 **6.4 HTTP Redirect/POST binding**

723 This section utilizes materials from [ShibMarlena and [Rescorla-Sec] and is derived from material in the
724 SAML 1.1 Bindings and Profiles specification [SAML11Bind].

725 **6.4.1 Stolen Assertion**

726 **Threat:** If an eavesdropper can copy the real user’s SAML response and included assertions, then the
727 eavesdropper could construct an appropriate POST body and be able to impersonate the user at the
728 destination site.

729 **Countermeasures:** Confidentiality MUST be provided whenever a response is communicated between a
730 site and the user’s browser. This provides protection against an eavesdropper obtaining a real user’s
731 SAML response and assertions.

732 If an eavesdropper defeats the measures used to ensure confidentiality, additional countermeasures are
733 available:

- 734 • The Identity Provider and Service Provider sites SHOULD make some reasonable effort to
735 ensure that clock settings at both sites differ by at most a few minutes. Many forms of time
736 synchronization service are available, both over the Internet and from proprietary sources.
- 737 • When a non-SSO SAML profile uses the POST binding it must ensure that the receiver can
738 perform timely subject confirmation. To this end, a SAML authentication assertion for the
739 principal MUST be included in the POSTed form response.
- 740 • Values for `NotBefore` and `NotOnOrAfter` attributes of SSO assertions SHOULD have the
741 shortest possible validity period consistent with successful communication of the assertion from
742 Identity Provider to Service Provider site. This is typically on the order of a few minutes. This
743 ensures that a stolen assertion can only be used successfully within a small time window.
- 744 • The Service Provider site MUST check the validity period of all assertions obtained from the

745 Identity Provider site and reject expired assertions. A Service Provider site MAY choose to
746 implement a stricter test of validity for SSO assertions, such as requiring the assertion's
747 `IssueInstant` or `AuthenticationInstant` attribute value to be within a few minutes of the
748 time at which the assertion is received at the Service Provider site.

749 • If a received authentication statement includes a `<saml:SubjectLocality>` element with the
750 IP address of the user, the Service Provider site MAY check the browser IP address against the
751 IP address contained in the authentication statement.

752 6.4.2 Man In the Middle Attack

753 **Threat:** Since the Service Provider site obtains bearer SAML assertions from the user by means of an
754 HTML form, a malicious site could impersonate the user at some new Service Provider site. The new
755 Service Provider site would believe the malicious site to be the subject of the assertion.

756 **Countermeasures:** The Service Provider site MUST check the Recipient attribute of the SAML response
757 to ensure that its value matches the `https://<assertion consumer host name and path>`. As the
758 response is digitally signed, the `Recipient` value cannot be altered by the malicious site.

759 6.4.3 Forged Assertion

760 **Threat:** A malicious user, or the browser user, could forge or alter a SAML assertion.

761 **Countermeasures:** The browser/POST profile requires the SAML response carrying SAML assertions to
762 be signed, thus providing both message integrity and authentication. The Service Provider site MUST
763 verify the signature and authenticate the issuer.

764 6.4.4 Browser State Exposure

765 **Threat:** The browser/POST profile involves uploading of assertions from the web browser to a Service
766 Provider site. This information is available as part of the web browser state and is usually stored in
767 persistent storage on the user system in a completely unsecured fashion. The threat here is that the
768 assertion may be "reused" at some later point in time.

769 **Countermeasures:** Assertions communicated using this profile must always have short lifetimes and
770 should have a `<OneTimeUse>` SAML assertion `<Conditions>` element. Service Provider sites are
771 expected to ensure that the assertions are not re-used.

772 6.4.5 Replay

773 **Threat:** Replay attacks amount to resubmission of the form in order to access a protected resource
774 fraudulently.

775 **Countermeasures:** The profile mandates that the assertions transferred have the one-use property at the
776 Service Provider site, preventing replay attacks from succeeding.

777 6.4.6 Modification or Exposure of state information

778 **Threat:** Relay state tampering or fabrication

779 Some of the messages may carry a `<RelayState>` element, which is recommended to be integrity-
780 protected by the producer and optionally confidentiality- protected. If these practices are not followed, an
781 adversary could trigger unwanted side effects. In addition, by not confidentiality-protecting the value of this
782 element, a legitimate system entity could inadvertently expose information to the identity provider or a
783 passive attacker.

784 **Countermeasure:** Follow the recommended practice of confidentiality- and integrity- protecting the
785 RelayState data. Note: Because the value of this element is both produced and consumed by the same
786 system entity, symmetric cryptographic primitives could be utilized

787 6.5 HTTP Artifact Binding

788 This section utilizes materials from [ShibMarlena and [Rescorla-Sec] and is derived from material in the
789 SAML 1.1 Bindings and Profiles specification [SAML11Bind].

790 6.5.1 Stolen Artifact

791 **Threat:** If an eavesdropper can copy the real user's SAML artifact, then the eavesdropper could construct
792 a URL with the real user's SAML artifact and be able to impersonate the user at the destination site.

793 **Countermeasures:** Confidentiality **MUST** be provided whenever an artifact is communicated between a
794 site and the user's browser. This provides protection against an eavesdropper gaining access to a real
795 user's SAML artifact.

796 If an eavesdropper defeats the measures used to ensure confidentiality, additional countermeasures are
797 available:

- 798 • The source and destination sites **SHOULD** make some reasonable effort to ensure that clock
799 settings at both sites differ by at most a few minutes. Many forms of time synchronization service
800 are available, both over the Internet and from proprietary sources.
- 801 • The source site **SHOULD** track the time difference between when a SAML artifact is generated
802 and placed on a URL line and when a `<samlp:Request>` message carrying the artifact is
803 received from the destination. A maximum time limit of a few minutes is recommended. Should
804 an assertion be requested by a destination site query beyond this time limit, the source site
805 **MUST** not provide the assertions to the destination site.
- 806 • It is possible for the source site to create SSO assertions either when the corresponding SAML
807 artifact is created or when a `<samlp:Request>` message carrying the artifact is received from
808 the destination. The validity period of the assertion **SHOULD** be set appropriately in each case:
809 longer for the former, shorter for the latter.
- 810 • Values for `NotBefore` and `NotOnOrAfter` attributes of SSO assertions **SHOULD** have the
811 shortest possible validity period consistent with successful communication of the assertion from
812 source to destination site. This is typically on the order of a few minutes. This ensures that a
813 stolen artifact can only be used successfully within a small time window.
- 814 • The destination site **MUST** check the validity period of all assertions obtained from the source
815 site and reject expired assertions. A destination site **MAY** choose to implement a stricter test of
816 validity for SSO assertions, such as requiring the assertion's `IssueInstant` or
817 `AuthenticationInstant` attribute value to be within a few minutes of the time at which the
818 assertion is received at the destination site.
- 819 • If a received authentication statement includes a `<saml:SubjectLocality>` element with the
820 IP address of the user, the destination site **MAY** check the browser IP address against the IP
821 address contained in the authentication statement.

822 6.5.2 Attacks on the SAML Protocol Message Exchange

823 **Threat:** The message exchange used by the Service Provider to obtain an assertion from the Identity
824 Provider could be attacked in a variety of ways, including artifact or assertion theft, replay, message
825 insertion or modification, and MITM (man-in-the-middle attack).

826 **Countermeasures:** The requirement for the use of a SAML protocol binding with the properties of
827 bilateral authentication, message integrity, and confidentiality defends against these attacks.

828 6.5.3 Malicious Destination Site

829 **Threat:** Since the Service Provider obtains artifacts from the user, a malicious site could impersonate the
830 user at some new Service Provider site. The new Service Provider site would obtain assertions from the
831 Identity Provider site and believe the malicious site to be the user.

832 **Countermeasures:** The new Service Provider site will need to authenticate itself to the Identity Provider

833 site so as to obtain the SAML assertions corresponding to the SAML artifacts. There are two cases to
834 consider:

- 835 1. If the new Service Provider site has no relationship with the Identity Provider site, it will be unable to
836 authenticate and this step will fail.
- 837 2. If the new Service Provider site has an existing relationship with the Identity Provider site, the
838 Identity Provider site will determine that assertions are being requested by a site other than that to
839 which the artifacts were originally sent. In such a case, the Identity Provider site MUST not provide
840 the assertions to the new Service Provider site.

841 **6.5.4 Forged SAML Artifact**

842 **Threat:** A malicious user could forge a SAML artifact.

843 **Countermeasures:** The Bindings specification provides specific recommendations regarding the
844 construction of a SAML artifact such that it is infeasible to guess or construct the value of a current, valid,
845 and outstanding assertion handle. A malicious user could attempt to repeatedly “guess” a valid SAML
846 artifact value (one that corresponds to an existing assertion at a Identity Provider site), but given the size
847 of the value space, this action would likely require a very large number of failed attempts. An Identity
848 Provider site SHOULD implement measures to ensure that repeated attempts at querying against non-
849 existent artifacts result in an alarm.

850 **6.5.5 Browser State Exposure**

851 **Threat:** The SAML browser/artifact profile involves “downloading” of SAML artifacts to the web browser
852 from an Identity Provider site. This information is available as part of the web browser state and is usually
853 stored in persistent storage on the user system in a completely unsecured fashion. The threat here is that
854 the artifact may be “reused” at some later point in time.

855 **Countermeasures:** The “one-use” property of SAML artifacts ensures that they cannot be reused from a
856 browser. Due to the recommended short lifetimes of artifacts and mandatory SSO assertions, it is difficult
857 to steal an artifact and reuse it from some other browser at a later time.

858 **6.5.6 Replay**

859 **Threat:** Reuse of an artifact by repeating protocol messages

860 **Countermeasures:** The threat of replay as a reuse of an artifact is addressed by the requirement that
861 each artifact is a one-time-use item. Systems should track cases where multiple requests are made
862 referencing the same artifact, as this situation may represent intrusion attempts.

863 The threat of replay on the original request that results in the assertion generation is not addressed by
864 SAML, but should be mitigated by the original authentication process.

865 **6.6 SAML URI Binding**

866 **6.6.1 Substitution**

867 **Threat:** Substitution of assertion with another by substitution of URI reference. Given that a URI is
868 opaque to the receiver it is hard to validate the integrity.

869 **Countermeasures:** Where this is a concern, transport layer integrity protection such as with SSL/TLS is
870 required.

871 7 SAML Profile Security Considerations

872 The SAML profiles specification [SAMLProf] defines profiles of SAML, which are sets of rules describing
873 how to embed SAML assertions into and extract them from a framework or protocol.

874 7.1 Web Browser Single Sign-On (SSO) Profiles

875 Note that user authentication at the source site is explicitly out of scope, as are issues related to this
876 source site authentication. The key notion is that the source system entity must be able to ascertain that
877 the authenticated client system entity that it is interacting with is the same as the one in the next
878 interaction step. One way to accomplish this is for these initial steps to be performed using TLS as a
879 session layer underneath the protocol being used for this initial interaction (likely HTTP).

880 7.1.1 SSO Profile

881 7.1.1.1 Eavesdropping

882 **Threat:** The possibility of eavesdropping exists in all web browser cases.

883 **Countermeasures:** In cases where confidentiality is required (bearing in mind that any assertion that is
884 not sent securely, along with the requests associated with it, is available to the malicious eavesdropper),
885 HTTP traffic needs to take place over a transport that ensures confidentiality. HTTP over TLS/SSL
886 [RFC2246] and the IP Security Protocol [IPsec] meet this requirement.

887 The following sections provide more detail on the eavesdropping threat.

888 7.1.1.2 Theft of the User Authentication Information

889 **Threat:** In the case where the subject authenticates to the source site by revealing reusable
890 authentication information, for example, in the form of a password, theft of the authentication information
891 will enable an adversary to impersonate the subject.

892 **Countermeasures:** In order to avoid this problem, the connection between the subject's browser and the
893 source site must implement a confidentiality safeguard. In addition, steps must be taken by either the
894 subject or the destination site to ensure that the source site is genuinely the expected and trusted source
895 site before revealing the authentication information. Using HTTP over TLS can be used to address this
896 concern.

897 7.1.1.3 Theft of the Bearer Token

898 **Threat:** In the case where the authentication assertion contains the assertion bearer's authentication
899 protocol identifier, theft of the artifact will enable an adversary to impersonate the subject.

900 **Countermeasures:** Each of the following methods decreases the likelihood of this happening:

- 901 • The destination site implements a confidentiality safeguard on its connection with the subject's
902 browser.
- 903 • The subject or destination site ensures (out of band) that the source site implements a
904 confidentiality safeguard on its connection with the subject's browser.
- 905 • The destination site verifies that the subject's browser was directly redirected by a source site
906 that directly authenticated the subject.
- 907 • The source site refuses to respond to more than one request for an assertion corresponding to
908 the same assertion ID.
- 909 • If the assertion contains a condition element of type **AudienceRestrictionType** that identifies a
910 specific domain, then the destination site verifies that it is a member of that domain.

- 911 • The connection between the destination site and the source site, over which the assertion ID is
912 passed, is implemented with a confidentiality safeguard.
- 913 • The destination site, in its communication with the source site, over which the assertion ID is
914 passed, must verify that the source site is genuinely the expected and trusted source site.

915 **7.1.1.4 Replay**

916 The possibility of a replay attack exists for this set of profiles. A replay attack can be used either to attempt
917 to deny service or to retrieve information fraudulently. The specific countermeasures depend on which
918 specific binding is used and are discussed above

919 **7.1.1.5 Message Insertion**

920 Message insertion attacks are discussed in the section on bindings.

921 **7.1.1.6 Message Deletion**

922 **Threat:** Deleting a message during any step of the interactions between the browser, SAML assertion
923 issuer, and SAML assertion consumer will cause the interaction to fail. It results in a denial of some
924 service but does not increase the exposure of any information.

925 **Countermeasures:** Use of an integrity protected transport channel addresses the threat of message
926 deletion when no intermediaries are present.

927 **7.1.1.7 Message Modification**

928 **Threat:** The possibility of alteration of the messages in the stream exists for this set of profiles. Some
929 potential undesirable results are as follows:

- 930 • Alteration of the initial request can result in rejection at the SAML issuer, or creation of an artifact
931 targeted at a different resource than the one requested
- 932 • Alteration of the artifact can result in denial of service at the SAML consumer.
- 933 • Alteration of the assertions themselves while in transit could result in all kinds of bad results (if
934 they are unsigned) or denial of service (if they are signed and the consumer rejects them).

935 **Countermeasures:**

936 To avoid message modification, the traffic needs to be transported by means of a system that guarantees
937 message integrity from endpoint to endpoint.

938 For the web browser-based profiles, the recommended method of providing message integrity in transit is
939 the use of HTTP over TLS/SSL with a cipher suite that provides data integrity checking.

940 **7.1.1.8 Man-in-the-Middle**

941 **Threat:** Man-in-the-middle attacks are particularly pernicious for this set of profiles. The MITM can relay
942 requests, capture the returned assertion (or artifact), and relay back a false one. Then the original user
943 cannot access the resource in question, but the MITM can do so using the captured resource.

944 **Countermeasures:** Preventing this threat requires a number of countermeasures. First, using a system
945 that provides strong bilateral authentication will make it much more difficult for a MITM to insert himself
946 into the conversation.

947 However the possibility still exists of a MITM who is purely acting as a bidirectional port forwarder, and
948 eavesdropping on the information with the intent to capture the returned assertion or handler (and possibly
949 alter the final return to the requester). Putting a confidentiality system in place will prevent eavesdropping.
950 Putting a data integrity system in place will prevent alteration of the message during port forwarding.

951 For this set of profiles, all the requirements of strong bilateral session authentication, confidentiality, and
952 data integrity can be met by the use of HTTP over TLS/SSL if the TLS/SSL layer uses an appropriate
953 cipher suite (strong enough encryption to provide confidentiality, and supporting data integrity) and
954 requires X509v3 certificates for authentication.

955 **7.1.1.9 Impersonation without Reauthentication**

956 **Threat:** Rogue user attempts to impersonate currently logged-in legitimate Principal and thereby gain
957 access to protected resources.

958 Once a Principal is successfully logged into an identity provider, subsequent <AuthnRequest> messages
959 from different service providers concerning that Principal will not necessarily cause the Principal to be
960 reauthenticated. Principals must, however, be authenticated unless the identity provider can determine
961 that an <AuthnRequest> is associated not only with the Principal's identity, but also with a validly
962 authenticated identity provider session for that Principal.

963 **Countermeasures:** In implementations where this threat is a concern, identity providers MUST maintain
964 state information concerning active sessions, and MUST validate the correspondence between an
965 <AuthnRequest> and an active session before issuing an <AuthnResponse> without first
966 authenticating the Principal. Cookies posted by identity providers MAY be used to support this validation
967 process, though Liberty does not mandate a cookie-based approach.

968 **7.1.2 Enhanced Client and Proxy Profile**

969 **7.1.2.1 Man in the Middle**

970 **Threat:** Intercept AuthnRequest and AuthnResponse SOAP messages, allowing subsequent Principal
971 impersonation.

972 A spurious system entity can interject itself as a man-in-the-middle (MITM) between the enhanced client
973 and a legitimate service provider, where it acts in the service provider role in interactions with the
974 enhanced client and in the enhanced client role in interactions with the legitimate service provider. In this
975 way, as a first step, the MITM is able to intercept the service provider's AuthnRequest and substitute any
976 URL of its choosing for the responseConsumerServiceURL value in the PAOS header block before
977 forwarding the AuthnRequest on to the enhanced client. Typically, the MITM will insert a URL value that
978 points back to itself. Then, if the enhanced client subsequently receives an AuthnResponse from the
979 identity provider and subsequently sends the contained AuthnResponse to the
980 responseConsumerServiceURL received from the MITM, the MITM will be able to masquerade as the
981 Principal at the legitimate service provider.

982 **Countermeasure:** The identity provider specifies to the enhanced client the address to which the
983 enhanced client must send the :AuthnResponse. The responseConsumerServiceURL in the PAOS
984 header is only used for error responses from the enhanced client – as specified in the profile.

985 **7.1.2.2 Denial of Service**

986 **Threat:** Change an AuthnRequest SOAP request so that it cannot be processed, such as by changing
987 the PAOS header block service attribute value to an unknown value or by changing the ECP header block
988 ProviderID or IDPList to cause the request to fail.

989 **Countermeasures:** Provide integrity protection for the SOAP message, by using SOAP Message Security
990 or SSL/TLS.

991 **7.1.3 Identity Provider Discovery Profile**

992 **Threat:** Cookie poisoning attack, where parameters within the cookie are modified, to cause discovery of
993 an fraudulent identity provider for example.

994 **Countermeasures:** The specific mechanism of using a common domain limits the feasibility of this threat.

995 **7.1.4 Single Logout Profile**

996 **Threat:** Passive attacker can collect a Principal's name identifier

997 During the initial steps, a passive attacker can collect the <LogoutRequest> information when it is issued
998 in the redirect. Exposing these data poses a privacy threat.

999 **Countermeasures:** All exchanges should be conducted over a secure transport such as SSL or TLS.
1000 **Threat:** Unsigned <LogoutRequest> message
1001 An Unsigned <LogoutRequest> could be injected by a spurious system entity thus denying service to
1002 the Principal. Assuming that the NameIdentifier can be deduced or derived then it is conceivable that the
1003 user agent could be directed to deliver a fabricated <LogoutRequest> message.
1004 **Countermeasures:** Sign the <LogoutRequest> message. The identity provider can also verify the
1005 identity of a Principal in the absence of a signed request.

1006 **7.2 Name Identifier Management Profiles**

1007 **Threat:** Allow system entities to correlate information or otherwise inappropriately expose identity
1008 information, harming privacy.
1009 **Countermeasures:** IDP must take care to use different name identifiers with different service providers
1010 for same principal. The IDP SHOULD encrypt the name identifier it returns to the service provider,
1011 allowing subsequent interactions to use an opaque identifier.

1012 **7.3 Attribute Profiles**

1013 Threats related to bindings associated with attribute profiles are discussed above. No additional profile-
1014 specific threats are known.

1015

8 Summary

1016 Security and privacy must be addressed in a systemic manner, considering human issues such as social
1017 engineering attacks, policy issues, key management and trust management, secure implementation and
1018 other factors outside the scope of this document. Security technical solutions have a cost, so
1019 requirements and policy alternatives must also be considered, as must legal and regulatory requirements.

1020 This non-normative document summarizes general security issues and approaches as well as specific
1021 threats and countermeasures for the use of SAML assertions, protocols, bindings and profiles in a secure
1022 manner that maintains privacy. Normative requirements are specified in the normative SAML
1023 specifications.

- 1145 • Marlena Erdos, IBM
- 1146 • Marc Chanliau, Netegrity
- 1147 • Chris McLaren, Netegrity
- 1148 • Lynne Rosenthal, NIST
- 1149 • Mark Skall, NIST
- 1150 • Simon Godik, Overxeer
- 1151 • Charles Norwood, SAIC
- 1152 • Evan Prodromou, Securant
- 1153 • Robert Griffin, RSA Security (former editor)
- 1154 • Sai Allarvarpu, Sun Microsystems
- 1155 • Chris Ferris, Sun Microsystems
- 1156 • Emily Xu, Sun Microsystems
- 1157 • Mike Myers, Traceroute Security
- 1158 • Phillip Hallam-Baker, VeriSign (former editor)
- 1159 • James Vanderbeek, Vodafone
- 1160 • Mark O'Neill, Vordel
- 1161 • Tony Palmer, Vordel

1162 Finally, the editors wish to acknowledge the following people for their contributions of material used as
1163 input to the OASIS Security Assertions Markup Language specifications:

- 1164 • Thomas Gross, IBM
- 1165 • Birgit Pfitzmann, IBM

1166 **Appendix B. Notices**

1167 OASIS takes no position regarding the validity or scope of any intellectual property or other rights that
1168 might be claimed to pertain to the implementation or use of the technology described in this document or
1169 the extent to which any license under such rights might or might not be available; neither does it represent
1170 that it has made any effort to identify any such rights. Information on OASIS's procedures with respect to
1171 rights in OASIS specifications can be found at the OASIS website. Copies of claims of rights made
1172 available for publication and any assurances of licenses to be made available, or the result of an attempt
1173 made to obtain a general license or permission for the use of such proprietary rights by implementors or
1174 users of this specification, can be obtained from the OASIS Executive Director.

1175 OASIS invites any interested party to bring to its attention any copyrights, patents or patent applications, or
1176 other proprietary rights which may cover technology that may be required to implement this specification.
1177 Please address the information to the OASIS Executive Director.

1178 **Copyright © OASIS Open 2004. All Rights Reserved.**

1179 This document and translations of it may be copied and furnished to others, and derivative works that
1180 comment on or otherwise explain it or assist in its implementation may be prepared, copied, published and
1181 distributed, in whole or in part, without restriction of any kind, provided that the above copyright notice and
1182 this paragraph are included on all such copies and derivative works. However, this document itself may
1183 not be modified in any way, such as by removing the copyright notice or references to OASIS, except as
1184 needed for the purpose of developing OASIS specifications, in which case the procedures for copyrights
1185 defined in the OASIS Intellectual Property Rights document must be followed, or as required to translate it
1186 into languages other than English.

1187 The limited permissions granted above are perpetual and will not be revoked by OASIS or its successors
1188 or assigns.

1189 This document and the information contained herein is provided on an "AS IS" basis and OASIS
1190 DISCLAIMS ALL WARRANTIES, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO ANY
1191 WARRANTY THAT THE USE OF THE INFORMATION HEREIN WILL NOT INFRINGE ANY RIGHTS OR
1192 ANY IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE.
