

# Web Services Security: SOAP Message Security 1.1 (WS-Security 2004)

**Draft - 11 September, 2005**

## OASIS identifier:

{product-productVersion-artifactType-stage-descriptiveName-revision.form (Word) (PDF)  
(HTML)}

## Location:

<http://docs.oasis-open.org/wss/2005/xx/wss-v1.1-spec-draft-SOAPMessageSecurity-01>

## Technical Committee:

**Web Service Security (WSS)**

## Chairs:

**Kelvin Lawrence, IBM**

**Chris Kaler, Microsoft**

## Editors:

**Anthony Nadalin, IBM**

**Chris Kaler, Microsoft**

**Ronald Monzillo, Sun**

**Phillip Hallam-Baker, Verisign**

## Abstract:

This specification describes enhancements to SOAP messaging to provide message integrity and confidentiality. The specified mechanisms can be used to accommodate a wide variety of security models and encryption technologies.

This specification also provides a general-purpose mechanism for associating security tokens with message content. No specific type of security token is required, the specification is designed to be extensible (i.e., support multiple security token formats). For example, a client might provide one format for proof of identity and provide another format for proof that they have a particular business certification.

36

Additionally, this specification describes how to encode binary security tokens, a framework for XML-based tokens, and how to include opaque encrypted keys. It also includes extensibility mechanisms that can be used to further describe the characteristics of the tokens that are included with a message.

## 50 Notices

51 OASIS takes no position regarding the validity or scope of any intellectual property or other rights  
52 that might be claimed to pertain to the implementation or use of the technology described in this  
53 document or the extent to which any license under such rights might or might not be available;  
54 neither does it represent that it has made any effort to identify any such rights. Information on  
55 OASIS's procedures with respect to rights in OASIS specifications can be found at the OASIS  
56 website. Copies of claims of rights made available for publication and any assurances of licenses  
57 to be made available, or the result of an attempt made to obtain a general license or permission  
58 for the use of such proprietary rights by implementers or users of this specification, can be  
59 obtained from the OASIS Executive Director.

60  
61 OASIS invites any interested party to bring to its attention any copyrights, patents or patent  
62 applications, or other proprietary rights which may cover technology that may be required to  
63 implement this specification. Please address the information to the OASIS Executive Director.

170

# 1 Introduction

171  
172  
173  
174

This OASIS specification is the result of significant new work by the WSS Technical Committee and supersedes the input submissions, Web Service Security (WS-Security) Version 1.0 April 5, 2002 and Web Services Security Addendum Version 1.0 August 18, 2002.

175  
176  
177  
178  
179

This specification proposes a standard set of SOAP [SOAP11, SOAP12] extensions that can be used when building secure Web services to implement message content integrity and confidentiality. This specification refers to this set of extensions and modules as the “Web Services Security: SOAP Message Security” or “WSS: SOAP Message Security”.

180  
181  
182  
183  
184

This specification is flexible and is designed to be used as the basis for securing Web services within a wide variety of security models including PKI, Kerberos, and SSL. Specifically, this specification provides support for multiple security token formats, multiple trust domains, multiple signature formats, and multiple encryption technologies. The token formats and semantics for using these are defined in the associated profile documents.

185  
186  
187  
188  
189

This specification provides three main mechanisms: ability to send security tokens as part of a message, message integrity, and message confidentiality. These mechanisms by themselves do not provide a complete security solution for Web services. Instead, this specification is a building block that can be used in conjunction with other Web service extensions and higher-level application-specific protocols to accommodate a wide variety of security models and security technologies.

190  
191  
192  
193  
194  
195

These mechanisms can be used independently (e.g., to pass a security token) or in a tightly coupled manner (e.g., signing and encrypting a message or part of a message and providing a security token or token path associated with the keys used for signing and encryption).

196

## 1.1 Goals and Requirements

197  
198  
199

The goal of this specification is to enable applications to conduct secure SOAP message exchanges.

200  
201  
202  
203

This specification is intended to provide a flexible set of mechanisms that can be used to construct a range of security protocols; in other words this specification intentionally does not describe explicit fixed security protocols.

204  
205  
206  
207

As with every security protocol, significant efforts must be applied to ensure that security protocols constructed using this specification are not vulnerable to any one of a wide range of attacks. The examples in this specification are meant to illustrate the syntax of these mechanisms and are not intended as examples of combining these mechanisms in secure ways.

208  
209  
210

The focus of this specification is to describe a single-message security language that provides for message security that may assume an established session, security context and/or policy agreement.

211  
212

The requirements to support secure message exchange are listed below.

213 **1.1.1 Requirements**

- 214 The Web services security language must support a wide variety of security models. The
- 215 following list identifies the key driving requirements for this specification:
- 216 | Multiple security token formats
- 217 | Multiple trust domains
- 218 | Multiple signature formats
- 219 | Multiple encryption technologies
- 220 | End-to-end message content security and not just transport-level security

← - - - - **Formatted:** No bullets or numbering

221 **1.1.2 Non-Goals**

- 222 The following topics are outside the scope of this document:
- 223
- 224 | Establishing a security context or authentication mechanisms.
- 225 | Key derivation.
- 226 | Advertisement and exchange of security policy.
- 227 | How trust is established or determined.
- 228 | Non-repudiation.
- 229

← - - - - **Formatted:** No bullets or numbering

## 230 2 Notations and Terminology

231 This section specifies the notations, namespaces, and terminology used in this specification.

### 232 2.1 Notational Conventions

233 The keywords "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD",  
234 "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be  
235 interpreted as described in RFC 2119.

236  
237 When describing abstract data models, this specification uses the notational convention used by  
238 the XML Infoset. Specifically, abstract property names always appear in square brackets (e.g.,  
239 [some property]).

240  
241 When describing concrete XML schemas, this specification uses a convention where each  
242 member of an element's [children] or [attributes] property is described using an XPath-like  
243 notation (e.g., /x:MyHeader/x:SomeProperty/@value1). The use of {any} indicates the presence  
244 of an element wildcard (<xs:any/>). The use of @{any} indicates the presence of an attribute  
245 wildcard (<xs:anyAttribute/>).

246  
247 Readers are presumed to be familiar with the terms in the Internet Security Glossary [GLOS].

### 248 2.2 Namespaces

249 Namespace URIs (of the general form "some-URI") represents some application-dependent or  
250 context-dependent URI as defined in RFC 2396 [URI].

251  
252 This specification is backwardly compatible with version 1.0. This means that URIs and schema  
253 elements defined in 1.0 remain unchanged and new schema elements and constants are defined  
254 using 1.1 namespaces and URIs.

255  
256 The XML namespace URIs that MUST be used by implementations of this specification are as  
257 follows (note that elements used in this specification are from various namespaces):

```
258 http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-  
259 secext-1.0.xsd  
260 http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-  
261 utility-1.0.xsd  
262 http://docs.oasis-open.org/wss/2005/xx/oasis-2005xx-wss-wssecurity-  
263 secext-1.1.xsd  
264
```

265  
266 This specification is designed to work with the general SOAP [SOAP11, SOAP12] message  
267 structure and message processing model, and should be applicable to any version of SOAP. The  
268 current SOAP 1.1 namespace URI is used herein to provide detailed examples, but there is no  
269 intention to limit the applicability of this specification to a single version of SOAP.

270

271 The namespaces used in this document are shown in the following table (note that for brevity, the  
 272 examples use the prefixes listed below but do not include the URIs – those listed below are  
 273 assumed).  
 274

Prefix	Namespace
ds	http://www.w3.org/2000/09/xmldsig#
S11	http://schemas.xmlsoap.org/soap/envelope/
S12	http://www.w3.org/2003/05/soap-envelope
wsse	http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-secext-1.0.xsd
wsse11	http://docs.oasis-open.org/wss/2005/xx/oasis-2005xx-wss-wssecurity-secext-1.1.xsd
wsu	http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-utility-1.0.xsd
xenc	http://www.w3.org/2001/04/xmlenc#

275 The URLs provided for the *wsse* and *wsu* namespaces can be used to obtain the schema files.  
 276

277  
 278 | URI fragments defined in this document are relative to the following base URI unless otherwise  
 279 stated:  
 280 http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0

## 281 2.3 Acronyms and Abbreviations

282 The following (non-normative) table defines acronyms and abbreviations for this document.  
 283

Term	Definition
HMAC	Keyed-Hashing for Message Authentication
SHA-1	Secure Hash Algorithm 1
SOAP	Simple Object Access Protocol
URI	Uniform Resource Identifier
XML	Extensible Markup Language

## 284 2.4 Terminology

285 Defined below are the basic definitions for the security terminology used in this specification.  
 286

Deleted: 28

Deleted: June

287 **Claim** – A *claim* is a declaration made by an entity (e.g. name, identity, key, group, privilege,  
288 capability, etc).

289  
290 **Claim Confirmation** – A *claim confirmation* is the process of verifying that a claim applies to  
291 an entity.

292  
293 **Confidentiality** – *Confidentiality* is the property that data is not made available to  
294 unauthorized individuals, entities, or processes.

295  
296 **Digest** – A *digest* is a cryptographic checksum of an octet stream.

297  
298 **Digital Signature** – A digital signature is a value computed with a cryptographic algorithm  
299 and bound to data in such a way that intended recipients of the data can use the digital signature  
300 to verify that the data has not been altered and/or has originated from the signer of the message,  
301 providing message integrity and authentication. The digital signature can be computed and  
302 verified with symmetric key algorithms, where the same key is used for signing and verifying, or  
303 with asymmetric key algorithms, where different keys are used for signing and verifying (a private  
304 and public key pair are used).

Deleted: In this document, digital signature and signature are used interchangeably and have the same meaning.

305  
306 **End-To-End Message Level Security** - *End-to-end message level security* is  
307 established when a message that traverses multiple applications (one or more SOAP  
308 intermediaries) within and between business entities, e.g. companies, divisions and business  
309 units, is secure over its full route through and between those business entities. This includes not  
310 only messages that are initiated within the entity but also those messages that originate outside  
311 the entity, whether they are Web Services or the more traditional messages.

312  
313 **Integrity** – *Integrity* is the property that data has not been modified.

314  
315 **Message Confidentiality** - *Message Confidentiality* is a property of the message and  
316 encryption is the mechanism by which this property of the message is provided.

317  
318 **Message Integrity** - *Message Integrity* is a property of the message and digital signature is a  
319 mechanism by which this property of the message is provided.

320  
321 **Signature** - In this document, signature and digital signature are used interchangeably and  
322 have the same meaning.

Deleted: A signature is a value computed with a cryptographic algorithm and bound to data in such a way that intended recipients of the data can use the signature to verify that the data has not been altered and/or has originated from the signer of the message, providing message integrity and authentication. The signature can be computed and verified with symmetric key algorithms, where the same key is used for signing and verifying, or with asymmetric key algorithms, where different keys are used for signing and verifying (a private and public key pair are used).

323  
324 **Security Token** – A *security token* represents a collection (one or more) of claims.  
325

Deleted:

Deleted: 28

Deleted: June

326  
327

328 **Signed Security Token** – A *signed security token* is a security token that is asserted and  
329 cryptographically signed by a specific authority (e.g. an X.509 certificate or a Kerberos ticket).  
330  
331 **Trust** - *Trust* is the characteristic that one entity is willing to rely upon a second entity to execute  
332 a set of actions and/or to make set of assertions about a set of subjects and/or scopes.

## 333 2.5 Note on Examples

334 The examples which appear in this document are only intended to illustrate the correct syntax of  
335 the features being specified. The examples are NOT intended to necessarily represent best  
336 practice for implementing any particular security properties.

337  
338 Specifically, the examples are constrained to contain only mechanisms defined in this document.  
339 The only reason for this is to avoid requiring the reader to consult other documents merely to  
340 understand the examples. It is NOT intended to suggest that the mechanisms illustrated  
341 represent best practice or are the strongest available to implement the security properties in  
342 question. In particular, mechanisms defined in other Token Profiles are known to be stronger,  
343 more efficient and/or generally superior to some of the mechanisms shown in the examples in this  
344 document.  
345

## 3 Message Protection Mechanisms

346

347 When securing SOAP messages, various types of threats should be considered. This includes,  
348 but is not limited to:

349

350 the message could be modified or read by attacker or  
351 an antagonist could send messages to a service that, while well-formed, lack appropriate security  
352 claims to warrant processing  
353 an antagonist could alter a message to the service which being well formed causes the service to  
354 process and respond to the client for an incorrect request.

355

356 To understand these threats this specification defines a message security model.

Formatted: No bullets or numbering

Deleted: antagonists

Formatted: Indent: Left: 0"

357

### 3.1 Message Security Model

358 This document specifies an abstract *message security model* in terms of security tokens  
359 combined with digital signatures to protect and authenticate SOAP messages.

360

361 Security tokens assert claims and can be used to assert the binding between authentication  
362 secrets or keys and security identities. An authority can vouch for or endorse the claims in a  
363 security token by using its key to sign or encrypt (it is recommended to use a keyed encryption)  
364 the security token thereby enabling the authentication of the claims in the token. An X.509 [X509]  
365 certificate, claiming the binding between one's identity and public key, is an example of a signed  
366 security token endorsed by the certificate authority. In the absence of endorsement by a third  
367 party, the recipient of a security token may choose to accept the claims made in the token based  
368 on its trust of the producer of the containing message.

369

370 Signatures are used to verify message origin and integrity. Signatures are also used by message  
371 producers to demonstrate knowledge of the key, typically from a third party, used to confirm the  
372 claims in a security token and thus to bind their identity (and any other claims occurring in the  
373 security token) to the messages they create.

374

375 It should be noted that this security model, by itself, is subject to multiple security attacks. Refer  
376 to the Security Considerations section for additional details.

377

378 Where the specification requires that an element be "processed" it means that the element type  
379 MUST be recognized to the extent that an appropriate error is returned if the element is not  
380 supported.

381

### 3.2 Message Protection

382 Protecting the message content from being disclosed (confidentiality) or modified without  
383 detection (integrity) are primary security concerns. This specification provides a means to protect  
384 a message by encrypting and/or digitally signing a body, a header, or any combination of them (or  
385 parts of them).

386

11, September, 2005  
Page 13 of 73

387 Message integrity is provided by XML Signature [XMLSIG] in conjunction with security tokens to  
388 ensure that modifications to messages are detected. The integrity mechanisms are designed to  
389 support multiple signatures, potentially by multiple SOAP actors/roles, and to be extensible to  
390 support additional signature formats.

391  
392 Message confidentiality leverages XML Encryption [XMLENC] in conjunction with security tokens  
393 to keep portions of a SOAP message confidential. The encryption mechanisms are designed to  
394 support additional encryption processes and operations by multiple SOAP actors/roles.  
395

396 This document defines syntax and semantics of signatures within a <wsse:Security> element.

397 This document does not constrain any signature appearing outside of a <wsse:Security>  
398 element.

Deleted: specify

### 399 3.3 Invalid or Missing Claims

400 A message recipient SHOULD reject messages containing invalid signatures, messages missing  
401 necessary claims or messages whose claims have unacceptable values. Such messages are  
402 unauthorized (or malformed). This specification provides a flexible way for the message producer  
403 to make a claim about the security properties by associating zero or more security tokens with the  
404 message. An example of a security claim is the identity of the producer; the producer can claim  
405 that he is Bob, known as an employee of some company, and therefore he has the right to send  
406 the message.

### 407 3.4 Example

408 The following example illustrates the use of a custom security token and associated signature.  
409 The token contains base64 encoded binary data conveying a symmetric key which, we assume,  
410 can be properly authenticated by the recipient. The message producer uses the symmetric key  
411 with an HMAC signing algorithm to sign the message. The message receiver uses its knowledge  
412 of the shared secret to repeat the HMAC key calculation which it uses to validate the signature  
413 and in the process confirm that the message was authored by the claimed user identity.  
414

```
415 (001) <?xml version="1.0" encoding="utf-8"?>
416 (002) <S11:Envelope xmlns:S11="..." xmlns:wsse="..." xmlns:wsu="..."

438 (014)         <ds:DigestValue>LyLsF0Pi4wPU...</ds:DigestValue>
439 (015)         </ds:Reference>
440 (016)         </ds:SignedInfo>
441 (017)         <ds:SignatureValue>Djbchm5gK...</ds:SignatureValue>
442 (018)         <ds:KeyInfo>
443 (019)             <wsse:SecurityTokenReference>
444 (020)                 <wsse:Reference URI="#MyID" />
445 (021)             </wsse:SecurityTokenReference>
446 (022)         </ds:KeyInfo>
447 (023)         </ds:Signature>
448 (024)         </wsse:Security>
449 (025)     </S11:Header>
450 (026)     <S11:Body wsu:Id="MsgBody">
451 (027)         <tru:StockSymbol xmlns:tru="http://fabrikam123.com/payloads">
452             QQQ
453         </tru:StockSymbol>
454 (028)     </S11:Body>
455 (029) </S11:Envelope>

```

Formatted: German (Germany)

456  
457 The first two lines start the SOAP envelope. Line (003) begins the headers that are associated  
458 with this SOAP message.

459  
460 Line (004) starts the <wsse:Security> header defined in this specification. This header  
461 contains security information for an intended recipient. This element continues until line (024).

462  
463 Lines (005) to (007) specify a custom token that is associated with the message. In this case, it  
464 uses an externally defined custom token format.

465  
466 Lines (008) to (023) specify a digital signature. This signature ensures the integrity of the signed  
467 elements. The signature uses the XML Signature specification identified by the ds namespace  
468 declaration in Line (002).

469  
470 Lines (009) to (016) describe what is being signed and the type of canonicalization being used.

471  
472 Line (010) specifies how to canonicalize (normalize) the data that is being signed. Lines (012) to  
473 (015) select the elements that are signed and how to digest them. Specifically, line (012)  
474 indicates that the <S11:Body> element is signed. In this example only the message body is  
475 signed; typically all critical elements of the message are included in the signature (see the  
476 Extended Example below).

Formatted: Indent: First line: 0"

477  
478 Line (017) specifies the signature value of the canonicalized form of the data that is being signed  
479 as defined in the XML Signature specification.

480  
481 Lines (018) to (022) provides information, partial or complete, as to where to find the security  
482 token associated with this signature. Specifically, lines (019) to (021) indicate that the security  
483 token can be found at (pulled from) the specified URL.

484  
485 Lines (026) to (028) contain the body (payload) of the SOAP message.

487

## 4 ID References

488

There are many motivations for referencing other message elements such as signature references or correlating signatures to security tokens. For this reason, this specification defines the `wsu:Id` attribute so that recipients need not understand the full schema of the message for processing of the security elements. That is, they need only "know" that the `wsu:Id` attribute represents a schema type of ID which is used to reference elements. However, because some key schemas used by this specification don't allow attribute extensibility (namely XML Signature and XML Encryption), this specification also allows use of their local ID attributes in addition to the `wsu:Id` attribute. As a consequence, when trying to locate an element referenced in a signature, the following attributes are considered:

492

493

494

495

496

497

- Local ID attributes on XML Signature elements
- Local ID attributes on XML Encryption elements
- Global `wsu:Id` attributes (described below) on elements
- Profile specific defined identifiers

501

502

503

504

505

In addition, when signing a part of an envelope such as the body, it is RECOMMENDED that an ID reference is used instead of a more general transformation, especially XPath [XPATH]. This is to simplify processing.

506

### 4.1 Id Attribute

507

508

509

510

511

512

513

514

There are many situations where elements within SOAP messages need to be referenced. For example, when signing a SOAP message, selected elements are included in the scope of the signature. XML Schema Part 2 [XMLSCHEMA] provides several built-in data types that may be used for identifying and referencing elements, but their use requires that consumers of the SOAP message either have or must be able to obtain the schemas where the identity or reference mechanisms are defined. In some circumstances, for example, intermediaries, this can be problematic and not desirable.

515

516

517

518

519

Consequently a mechanism is required for identifying and referencing elements, based on the SOAP foundation, which does not rely upon complete schema knowledge of the context in which an element is used. This functionality can be integrated into SOAP processors so that elements can be identified and referred to without dynamic schema discovery and processing.

520

521

522

This section specifies a namespace-qualified global attribute for identifying an element which can be applied to any element that either allows arbitrary attributes or specifically allows a particular attribute.

523

### 4.2 Id Schema

524

525

526

527

528

To simplify the processing for intermediaries and recipients, a common attribute is defined for identifying an element. This attribute utilizes the XML Schema ID type and specifies a common attribute for indicating this information for elements.

The syntax for this attribute is as follows:

WSS: SOAP Message Security (WS-Security 2004)  
Copyright © OASIS Open 2002-2005. All Rights Reserved.

11, September, 2005  
Page 16 of 73

Aligned at: 0.25" + Tab after: 0.5"  
+ Indent at: 0.5"

Deleted: 28

Deleted: June

529 `<anyElement wsu:Id="...">...</anyElement>`

530

531 The following describes the attribute illustrated above:

532 `../@wsu:Id`

533 This attribute, defined as type `xsd:ID`, provides a well-known attribute for specifying the  
534 local ID of an element.

535

536 Two `wsu:Id` attributes within an XML document MUST NOT have the same value.

537 Implementations MAY rely on XML Schema validation to provide rudimentary enforcement for  
538 intra-document uniqueness. However, applications SHOULD NOT rely on schema validation  
539 alone to enforce uniqueness.

540

541 This specification does not specify how this attribute will be used and it is expected that other  
542 specifications MAY add additional semantics (or restrictions) for their usage of this attribute.

543 The following example illustrates use of this attribute to identify an element:

544

545 `<x:myElement wsu:Id="ID1" xmlns:x="..."`  
546 `xmlns:wsu="..." />`

547

548 Conformant processors that do support XML Schema MUST treat this attribute as if it was  
549 defined using a global attribute declaration.

550

551 Conformant processors that do not support dynamic XML Schema or DTDs discovery and  
552 processing are strongly encouraged to integrate this attribute definition into their parsers. That is,  
553 to treat this attribute information item as if its PSVI has a [type definition] which {target  
554 namespace} is "`http://www.w3.org/2001/XMLSchema`" and which {type} is "ID." Doing so  
555 allows the processor to inherently know *how* to process the attribute without having to locate and  
556 process the associated schema. Specifically, implementations MAY support the value of the  
557 `wsu:Id` as the valid identifier for use as an XPointer [XPointer] shorthand pointer for  
558 interoperability with XML Signature references.

559

## 5 Security Header

560  
561  
562  
563  
564  
565  
566

The `<wsse:Security>` header block provides a mechanism for attaching security-related information targeted at a specific recipient in the form of a SOAP actor/role. This may be either the ultimate recipient of the message or an intermediary. Consequently, elements of this type may be present multiple times in a SOAP message. An active intermediary on the message path MAY add one or more new sub-elements to an existing `<wsse:Security>` header block if they are targeted for its SOAP node or it MAY add one or more new headers for additional targets.

567  
568  
569  
570  
571  
572  
573  
574  
575  
576  
577

As stated, a message MAY have multiple `<wsse:Security>` header blocks if they are targeted for separate recipients. **A message MUST NOT have multiple `<wsse:Security>` header blocks targeted (whether explicitly or implicitly) at the same recipient.** However, only one `<wsse:Security>` header block MAY omit the `S11:actor` or `S12:role` attributes. Two `<wsse:Security>` header blocks MUST NOT have the same value for `S11:actor` or `S12:role`. Message security information targeted for different recipients MUST appear in different `<wsse:Security>` header blocks. This is due to potential processing order issues (e.g. due to possible header re-ordering). The `<wsse:Security>` header block without a specified `S11:actor` or `S12:role` MAY be processed by anyone, but MUST NOT be removed prior to the final destination or endpoint.

578  
579  
580  
581  
582  
583  
584  
585

As elements are added to a `<wsse:Security>` header block, they SHOULD be prepended to the existing elements. As such, the `<wsse:Security>` header block represents the signing and encryption steps the message producer took to create the message. This prepending rule ensures that the receiving application can process sub-elements in the order they appear in the `<wsse:Security>` header block, because there will be no forward dependency among the sub-elements. Note that this specification does not impose any specific order of processing the sub-elements. The receiving application can use whatever order is required.

586  
587  
588  
589

When a sub-element refers to a key carried in another sub-element (for example, a signature sub-element that refers to a binary security token sub-element that contains the X.509 certificate used for the signature), the key-bearing element SHOULD be ordered to precede the key-using Element:

590  
591  
592  
593  
594  
595  
596  
597  
598  
599  
600  
601

```
<S11:Envelope>
  <S11:Header>
    ...
    <wsse:Security S11:actor="..." S11:mustUnderstand="...">
      ...
    </wsse:Security>
    ...
  </S11:Header>
  ...
</S11:Envelope>
```

602  
603  
604

The following describes the attributes and elements listed in the example above:

`/wsse:Security`

This is the header block for passing security-related message information to a recipient.

*/wsse:Security/@S11:actor*

This attribute allows a specific SOAP 1.1 [SOAP11] actor to be identified. This attribute is optional; however, no two instances of the header block may omit an actor or specify the same actor.

Deleted: P

*/wsse:Security/@S12:role*

This attribute allows a specific SOAP 1.2 [SOAP12] role to be identified. This attribute is optional; however, no two instances of the header block may omit a role or specify the same role.

*/wsse:Security/@S11:mustUnderstand*

This SOAP 1.1 [SOAP11] attribute is used to indicate whether a header entry is mandatory or optional for the recipient to process. The value of the mustUnderstand attribute is either "1" or "0". The absence of the SOAP mustUnderstand attribute is semantically equivalent to its presence with the value "0".

Deleted: P

*/wsse:Security/@S12:mustUnderstand*

This SOAP 1.2 [SPOAP12] attribute is used to indicate whether a header entry is mandatory or optional for the recipient to process. The value of the mustUnderstand attribute is either "true", "1", "false" or "0". The absence of the SOAP mustUnderstand attribute is semantically equivalent to its presence with the value "false".

Deleted: or

*/wsse:Security/{any}*

This is an extensibility mechanism to allow different (extensible) types of security information, based on a schema, to be passed. Unrecognized elements SHOULD cause a fault.

*/wsse:Security/@{any}*

This is an extensibility mechanism to allow additional attributes, based on schemas, to be added to the header. Unrecognized attributes SHOULD cause a fault.

All compliant implementations MUST be able to process a `<wsse:Security>` element.

All compliant implementations MUST declare which profiles they support and MUST be able to process a `<wsse:Security>` element including any sub-elements which may be defined by that profile. It is RECOMMENDED that undefined elements within the `<wsse:Security>` header not be processed.

The next few sections outline elements that are expected to be used within a `<wsse:Security>` header.

When a `<wsse:Security>` header includes a `mustUnderstand="true"` attribute:

The receiver MUST generate a SOAP fault if does not implement the WSS: SOAP Message Security specification corresponding to the namespace. Implementation means ability to interpret the schema as well as follow the required processing rules specified in WSS: SOAP Message Security.

Formatted: No bullets or numbering

The receiver MUST generate a fault if unable to interpret or process security tokens contained in the `<wsse:Security>` header block according to the corresponding WSS: SOAP Message Security token profiles.

## 6 Security Tokens

658 This chapter specifies some different types of security tokens and how they are attached to  
659 messages.

### 6.1 Attaching Security Tokens

661 This specification defines the `<wsse:Security>` header as a mechanism for conveying  
662 security information with and about a SOAP message. This header is, by design, extensible to  
663 support many types of security information.  
664

665 For security tokens based on XML, the extensibility of the `<wsse:Security>` header allows for  
666 these security tokens to be directly inserted into the header.

#### 6.1.1 Processing Rules

668 This specification describes the processing rules for using and processing XML Signature and  
669 XML Encryption. These rules MUST be followed when using any type of security token. Note  
670 that if signature or encryption is used in conjunction with security tokens, they MUST be used in a  
671 way that conforms to the processing rules defined by this specification.

#### 6.1.2 Subject Confirmation

673 This specification does not dictate if and how claim confirmation must be done; however, it does  
674 define how signatures may be used and associated with security tokens (by referencing the  
675 security tokens from the signature) as a form of claim confirmation.

## 6.2 User Name Token

### 6.2.1 Usernames

678 The `<wsse:UsernameToken>` element is introduced as a way of providing a username. This  
679 element is optionally included in the `<wsse:Security>` header.  
680 The following illustrates the syntax of this element:

```
681 <wsse:UsernameToken wsu:Id="...">  
682   <wsse:Username>...</wsse:Username>  
683 </wsse:UsernameToken>
```

685  
686 The following describes the attributes and elements listed in the example above:

687 */wsse:UsernameToken*

688 This element is used to represent a claimed identity.

690 */wsse:UsernameToken/@wsu:Id*

692 A string label for this security token. The `wsu:Id` allow for an open attribute model.  
693

694 */wsse:UsernameToken/wsse:Username*  
 695 This required element specifies the claimed identity.  
 696  
 697 */wsse:UsernameToken/wsse:Username/@{any}*  
 698 This is an extensibility mechanism to allow additional attributes, based on schemas, to be  
 699 added to the `<wsse:Username>` element.  
 700  
 701 */wsse:UsernameToken/{any}* ← **Formatted: Indent: Left: 0.5"**  
 702 This is an extensibility mechanism to allow different (extensible) types of security  
 703 information, based on a schema, to be passed. Unrecognized elements SHOULD cause  
 704 a fault.  
 705  
 706 */wsse:UsernameToken/@{any}*  
 707 This is an extensibility mechanism to allow additional attributes, based on schemas, to be  
 708 added to the `<wsse:UsernameToken>` element. Unrecognized attributes SHOULD  
 709 cause a fault.  
 710  
 711 All compliant implementations MUST be able to process a `<wsse:UsernameToken>` ← **Formatted: Indent: Left: 0.5"**  
 712 element.

713 The following illustrates the use of this:

```

714 <S11:Envelope xmlns:S11="..." xmlns:wsse="...">
715   <S11:Header>
716     ...
717     <wsse:Security>
718       <wsse:UsernameToken>
719         <wsse:Username>Zoe</wsse:Username>
720       </wsse:UsernameToken>
721     </wsse:Security>
722   </S11:Header>
723   ...
724 </S11:Envelope>
725
726
727
  
```

## 728 6.3 Binary Security Tokens

### 729 6.3.1 Attaching Security Tokens

730 For binary-formatted security tokens, this specification provides a  
 731 `<wsse:BinarySecurityToken>` element that can be included in the `<wsse:Security>`  
 732 header block.

### 733 6.3.2 Encoding Binary Security Tokens

734 Binary security tokens (e.g., X.509 certificates and Kerberos [KERBEROS] tickets) or other non-  
 735 XML formats require a special encoding format for inclusion. This section describes a basic  
 736 framework for using binary security tokens. Subsequent specifications MUST describe the rules  
 737 for creating and processing specific binary security token formats.  
 738

Deleted: 28  
 Deleted: June

739 The <wsse:BinarySecurityToken> element defines two attributes that are used to interpret  
 740 it. The ValueType attribute indicates what the security token is, for example, a Kerberos ticket.  
 741 The EncodingType tells how the security token is encoded, for example Base64Binary.  
 742 The following is an overview of the syntax:

```
743
744 <wsse:BinarySecurityToken wsu:Id=...
745                               EncodingType=...
746                               ValueType=.../>
747
```

748 The following describes the attributes and elements listed in the example above:

749 /wsse:BinarySecurityToken

750 This element is used to include a binary-encoded security token.

751 /wsse:BinarySecurityToken/@wsu:Id

752 An optional string label for this security token.

753 /wsse:BinarySecurityToken/@ValueType

754 The ValueType attribute is used to indicate the "value space" of the encoded binary  
 755 data (e.g. an X.509 certificate). The ValueType attribute allows a URI that defines the  
 756 value type and space of the encoded binary data. Subsequent specifications MUST  
 757 define the ValueType value for the tokens that they define. The usage of ValueType is  
 758 RECOMMENDED.

759 /wsse:BinarySecurityToken/@EncodingType

760 The EncodingType attribute is used to indicate, using a URI, the encoding format of the  
 761 binary data (e.g., base64 encoded). A new attribute is introduced, as there are issues  
 762 with the current schema validation tools that make derivations of mixed simple and  
 763 complex types difficult within XML Schema. The EncodingType attribute is interpreted  
 764 to indicate the encoding format of the element. The following encoding formats are pre-  
 765 defined:

URI	Description
#Base64Binary (default)	XML Schema base 64 encoding

Deleted: (note that the URI fragments are relative to the URI for this specification)

766 /wsse:BinarySecurityToken/@{any}

767 This is an extensibility mechanism to allow additional attributes, based on schemas, to be  
 768 added.

769 All compliant implementations MUST be able to process a <wsse:BinarySecurityToken>  
 770 element.

## 771 6.4 XML Tokens

772 This section presents a framework for using XML-based security tokens. Profile specifications  
 773 describe rules and processes for specific XML-based security token formats.

Deleted: 28  
 Deleted: June

## 780 **6.5 EncryptedData Token**

781 In certain cases it is desirable that the token included in the `<wsse:Security>` header be  
782 encrypted for the recipient processing role. In such a case the `<xenc:EncryptedData>`  
783 element MAY be used to contain a security token and included in the `<wsse:Security>`  
784 header. That is this specification defines the usage of `<xenc:EncryptedData>` to encrypt  
785 security tokens contained in `<wsse:Security>` header.

786  
787 It should be noted that token references are not made to the `<xenc:EncryptedData>` element,  
788 but instead to the token represented by the clear-text, once the `<xenc:EncryptedData>`  
789 element has been processed (decrypted). Such references utilize the token profile for the  
790 contained token. i.e., `<xenc:EncryptedData>` SHOULD NOT include an XML Id for  
791 referencing the contained security token.

792  
793 All `<xenc:EncryptedData>` tokens SHOULD either have an embedded encryption key or  
794 should be referenced by a separate encryption key.

795 When a `<xenc:EncryptedData>` token is processed, it is replaced in the message infoset with  
796 its decrypted form.

## 797 **6.6 Identifying and Referencing Security Tokens**

798 This specification also defines multiple mechanisms for identifying and referencing security  
799 tokens using the `wsu:Id` attribute and the `<wsse:SecurityTokenReference>` element (as  
800 well as some additional mechanisms). Please refer to the specific profile documents for the  
801 appropriate reference mechanism. However, specific extensions MAY be made to the  
802 `<wsse:SecurityTokenReference>` element.

803

## 7 Token References

804

This chapter discusses and defines mechanisms for referencing security tokens and other key bearing elements..

805

806

### 7.1 SecurityTokenReference Element

807

Digital signature and encryption operations require that a key be specified. For various reasons, the element containing the key in question may be located elsewhere in the message or completely outside the message. The `<wsse:SecurityTokenReference>` element provides an extensible mechanism for referencing security tokens and other key bearing elements.

808

809

810

811

812

The `<wsse:SecurityTokenReference>` element provides an open content model for referencing key bearing elements because not all of them support a common reference pattern. Similarly, some have closed schemas and define their own reference mechanisms. The open content model allows appropriate reference mechanisms to be used.

813

814

815

816

If a `<wsse:SecurityTokenReference>` is used outside of the security header processing block the meaning of the response and/or processing rules of the resulting references MUST be specified by the [the specific profile](#) and are out of scope of this specification.

819

The following illustrates the syntax of this element:

820

821

822

```
<wsse:SecurityTokenReference wsu:Id="...", wss11:TokenType="...",  
wsse:Usage="...", wsse:Usage="...">  
</wsse:SecurityTokenReference>
```

823

824

825

The following describes the elements defined above:

826

827

*/wsse:SecurityTokenReference*

829

This element provides a reference to a security token.

830

831

*/wsse:SecurityTokenReference/@wsu:Id*

832

A string label for this security token reference which names the reference. This attribute does not indicate the ID of what is being referenced, that SHOULD be done using a fragment URI in a `<wsse:Reference>` element within the `<wsse:SecurityTokenReference>` element.

833

834

835

836

837

*/wsse:SecurityTokenReference/@wss11:TokenType*

838

This optional attribute is used to identify, by URI, the type of the referenced token.

839

This specification recommends that token specific profiles define appropriate token type identifying URI values, and that these same profiles require that these values be specified in the profile defined reference forms.

840

841

842

843

When a `wss11:TokenType` attribute is specified in conjunction with a `wsse:KeyIdentifier/@ValueType` attribute or a `wsse:Reference/@ValueType`

858  
859

`/wsse:SecurityTokenReference/{any}`  
 This is an extensibility mechanism to allow different (extensible) types of security references, based on a schema, to be passed. Unrecognized elements SHOULD cause a fault.

860  
861  
862  
863

`/wsse:SecurityTokenReference/@{any}`  
 This is an extensibility mechanism to allow additional attributes, based on schemas, to be added to the header. Unrecognized attributes SHOULD cause a fault.

864  
865  
866

All compliant implementations MUST be able to process a `<wsse:SecurityTokenReference>` element.

867  
868  
869  
870  
871  
872

This element can also be used as a direct child element of `<ds:KeyInfo>` to indicate a hint to retrieve the key information from a security token placed somewhere else. In particular, it is RECOMMENDED, when using XML Signature and XML Encryption, that a `<wsse:SecurityTokenReference>` element be placed inside a `<ds:KeyInfo>` to reference the security token used for the signature or encryption.

873  
874  
875  
876  
877  
878  
879  
880

There are several challenges that implementations face when trying to interoperate. Processing the IDs and references requires the recipient to *understand* the schema. This may be an expensive task and in the general case impossible as there is no way to know the "schema location" for a specific namespace URI. As well, the primary goal of a reference is to uniquely identify the desired token. ID references are, by definition, unique by XML. However, other mechanisms such as "principal name" are not required to be unique and therefore such references may be not unique.

881  
882  
883  
884  
885  
886

This specification allows for the use of multiple reference mechanisms within a single SecurityTokenReference. When multiple references are present in a given SecurityTokenReference, they MUST resolve to a single token in common. Specific token profiles SHOULD define the reference mechanisms to be used.

- Deleted: 28
- Deleted: June

887 The following list provides a list of the specific reference mechanisms defined in WSS: SOAP  
888 Message Security in preferred order (i.e., most specific to least specific):  
889

- 890 • **Direct References** – This allows references to included tokens using URI fragments and  
891 external tokens using full URIs.
- 892 • **Key Identifiers** – This allows tokens to be referenced using an opaque value that  
893 represents the token (defined by token type/profile).
- 894 • **Key Names** – This allows tokens to be referenced using a string that matches an identity  
895 assertion within the security token. This is a subset match and may result in multiple  
896 security tokens that match the specified name.
- 897 • **Embedded References** - This allows tokens to be embedded (as opposed to a pointer  
898 to a token that resides elsewhere).

## 899 7.2 Direct References

900 The <wsse:Reference> element provides an extensible mechanism for directly referencing  
901 security tokens using URIs.

902 The following illustrates the syntax of this element:

```
903 <wsse:SecurityTokenReference wsu:Id="...">  
904   <wsse:Reference URI="..." ValueType="..." />  
905 </wsse:SecurityTokenReference>
```

906 The following describes the elements defined above:

907 /wsse:SecurityTokenReference/wsse:Reference

908 This element is used to identify an abstract URI location for locating a security token.

909 /wsse:SecurityTokenReference/wsse:Reference/@URI

910 This optional attribute specifies an abstract URI for where to find a security token. If a  
911 fragment is specified, then it indicates the local ID of the token being referenced.

912 /wsse:SecurityTokenReference/wsse:Reference/@ValueType

913 This optional attribute specifies a URI that is used to identify the *type* of token being  
914 referenced. This specification does not define any processing rules around the usage of  
915 this attribute, however, specifications for individual token types MAY define specific  
916 processing rules and semantics around the value of the URI and its interpretation. If this  
917 attribute is not present, the URI MUST be processed as a normal URI.

918 In this version of the specification the use of this attribute to identify the type of the  
919 referenced security token is deprecated. Profiles which require or recommend the use of  
920 this attribute to identify the type of the referenced security token SHOULD evolve to  
921 require or recommend the use of the

922 wsse:SecurityTokenReference/@wsse11:TokenType attribute to identify the type  
923 of the referenced token.

924 /wsse:SecurityTokenReference/wsse:Reference/{any}

Deleted: how it SHALL

Deleted: T

Deleted: 28

Deleted: June

933 This is an extensibility mechanism to allow different (extensible) types of security  
934 references, based on a schema, to be passed. Unrecognized elements SHOULD cause a  
935 fault.

936  
937 */wsse:SecurityTokenReference/wsse:Reference/@{any}*

938 This is an extensibility mechanism to allow additional attributes, based on schemas, to be  
939 added to the header. Unrecognized attributes SHOULD cause a fault.

940

941 The following illustrates the use of this element:

942

```
943 <wsse:SecurityTokenReference  
944   xmlns:wsse="...">  
945   <wsse:Reference  
946     URI="http://www.fabrikam123.com/tokens/Zoe"/>  
947 </wsse:SecurityTokenReference>
```

### 948 7.3 Key Identifiers

949 Alternatively, if a direct reference is not used, then it is RECOMMENDED that a key identifier be  
950 used to specify/reference a security token instead of a `<ds:KeyName>`. A KeyIdentifier is a  
951 value that can be used to uniquely identify a security token (e.g. a hash of the important elements  
952 of the security token). The exact value type and generation algorithm varies by security token  
953 type (and sometimes by the data within the token), Consequently, the values and algorithms are  
954 described in the token-specific profiles rather than this specification.

Deleted: to use

Deleted: bi

955  
956 The `<wsse:KeyIdentifier>` element SHALL is placed in the  
957 `<wsse:SecurityTokenReference>` element to reference a token using an identifier. This  
958 element SHOULD be used for all key identifiers.

Deleted: be

959  
960 The processing model assumes that the key identifier for a security token is constant.  
961 Consequently, processing a key identifier involves simply looking for a security token whose key  
962 identifier matches the specified constant. The `<wsse:KeyIdentifier>` element is only allowed  
963 inside a `<wsse:SecurityTokenReference>` element

Deleted: is

Deleted: a

Deleted: given

964 The following is an overview of the syntax:

965

```
966 <wsse:SecurityTokenReference>  
967   <wsse:KeyIdentifier wsu:Id="..."  
968                       ValueType="..."  
969                       EncodingType="...">  
970     ...  
971   </wsse:KeyIdentifier>  
972 </wsse:SecurityTokenReference>
```

973

974 The following describes the attributes and elements listed in the example above:

975

976 */wsse:SecurityTokenReference/wsse:KeyIdentifier*

977 This element is used to include a binary-encoded key identifier.

978

979 */wsse:SecurityTokenReference/wsse:KeyIdentifier/@wsu:Id*

980 An optional string label for this identifier.

994 The optional `EncodingType` attribute is used to indicate, using a URI, the encoding  
 995 format of the `KeyIdentifier` (`#Base64Binary`). This specification defines the  
 996 `EncodingType` URI values appearing in the following table. A token specific profile MAY  
 997 define additional token specific `EncodingType` URI values. A `KeyIdentifier` MUST  
 998 include an `EncodingType` attribute when its `ValueType` is not sufficient to identify its  
 999 encoding type. The base values defined in this specification are:

URI	Description
<code>#Base64Binary</code>	XML Schema base 64 encoding

- Formatted: Font: Courier New
- Deleted: used (Note that URI fragments are relative to this document's URI):

1001  
 1002 `/wsse:SecurityTokenReference/wsse:KeyIdentifier/{any}`  
 1003 This is an extensibility mechanism to allow additional attributes, based on schemas, to be  
 1004 added.

### 7.4 Embedded References

1006 In some cases a reference may be to an embedded token (as opposed to a pointer to a token  
 1007 that resides elsewhere). To do this, the `<wsse:Embedded>` element is specified within a  
 1008 `<wsse:SecurityTokenReference>` element. The `<wsse:Embedded>` element is only  
 1009 allowed inside a `<wsse:SecurityTokenReference>` element.  
 1010 The following is an overview of the syntax:

```

1011 <wsse:SecurityTokenReference>
1012   <wsse:Embedded wsu:Id="...">
1013     ...
1014   </wsse:Embedded>
1015 </wsse:SecurityTokenReference>
  
```

1017 The following describes the attributes and elements listed in the example above:

- 1018 `/wsse:SecurityTokenReference/wsse:Embedded`  
 1019 This element is used to embed a token directly within a reference (that is, to create a  
 1020 *local* or *literal* reference).
- 1021 `/wsse:SecurityTokenReference/wsse:Embedded/@wsu:Id`  
 1022 An optional string label for this element. This allows this embedded token to be  
 1023 referenced by a signature or encryption.
- 1024 `/wsse:SecurityTokenReference/wsse:Embedded/{any}`  
 1025 This is an extensibility mechanism to allow any security token, based on schemas, to be  
 1026 embedded. Unrecognized elements SHOULD cause a fault.
- 1027 `/wsse:SecurityTokenReference/wsse:Embedded/{any}`  
 1028 This is an extensibility mechanism to allow any security token, based on schemas, to be  
 1029 embedded. Unrecognized elements SHOULD cause a fault.
- 1030 `/wsse:SecurityTokenReference/wsse:Embedded/{any}`  
 1031 This is an extensibility mechanism to allow any security token, based on schemas, to be  
 1032 embedded. Unrecognized elements SHOULD cause a fault.
- 1033 `/wsse:SecurityTokenReference/wsse:Embedded/{any}`  
 1034 This is an extensibility mechanism to allow any security token, based on schemas, to be  
 1035 embedded. Unrecognized elements SHOULD cause a fault.

1036 The following example illustrates embedding a SAML assertion:  
 1037

- Deleted: 28
- Deleted: June

```

1038 <S11:Envelope xmlns:S11="..." xmlns:wsse="..." xmlns:wsu="...">
1039   <S11:Header>
1040     <wsse:Security>
1041       ...
1042       <wsse:SecurityTokenReference>
1043         <wsse:Embedded wsu:Id="tok1">
1044           <saml:Assertion xmlns:saml="...">
1045             ...
1046           </saml:Assertion>
1047         </wsse:Embedded>
1048       </wsse:SecurityTokenReference>
1049       ...
1050     </wsse:Security>
1051   </S11:Header>
1052   ...
1053 </S11:Envelope>

```

## 7.5 ds:KeyInfo

The <ds:KeyInfo> element (from XML Signature) can be used for carrying the key information and is allowed for different key types and for future extensibility. However, in this specification, the use of <wsse:BinarySecurityToken> is the RECOMMENDED mechanism to carry key material if the key type contains binary data. Please refer to the specific profile documents for the appropriate way to carry key material.

The following example illustrates use of this element to fetch a named key:

```

<ds:KeyInfo Id="..." xmlns:ds="http://www.w3.org/2000/09/xmldsig#">
  <ds:KeyName>CN=Hiroshi Maruyama, C=JP</ds:KeyName>
</ds:KeyInfo>

```

## 7.6 Key Names

It is strongly RECOMMENDED to use <wsse:KeyIdentifier> elements. However, if key names are used, then it is strongly RECOMMENDED that <ds:KeyName> elements conform to the attribute names in section 2.3 of RFC 2253 (this is recommended by XML Signature for <ds:X509SubjectName>) for interoperability.

Additionally, e-mail addresses, SHOULD conform to RFC 822:

```
EmailAddress=ckaler@microsoft.com
```

## 7.7 Encrypted Key reference

In certain cases, an <xenc:EncryptedKey> element MAY be used to carry key material encrypted for the recipient's key. This key material is henceforth referred to as *EncryptedKey*.

The *EncryptedKey* MAY be used to perform other cryptographic operations within the same message, such as signatures. The *EncryptedKey* MAY also be used for performing cryptographic operations in subsequent messages exchanged by the two parties. Two mechanisms are defined for referencing the *EncryptedKey*.

Deleted: EncryptedKey

Deleted: 28

Deleted: June

1083 | When referencing the EncryptedKey within the same message that contains the  
1084 | <xenc:EncryptedKey> element, the <ds:KeyInfo> element of the referencing construct  
1085 | MUST contain a <wsse:SecurityTokenReference>. The  
1086 | <wsse:SecurityTokenReference> element MUST contain a <wsse:Reference> element.

1087 |  
1088 | The URI attribute value of the <wsse:Reference> element MUST be set to the value of the ID  
1089 | attribute of the referenced <xenc:EncryptedKey> element that contains the EncryptedKey.

1090 | When referencing the EncryptedKey in a message that does not contain the  
1091 | <xenc:EncryptedKey> element, the <ds:KeyInfo> element of the referencing construct  
1092 | MUST contain a <wsse:SecurityTokenReference>. The  
1093 | <wsse:SecurityTokenReference> element MUST contain a <wsse:KeyIdentifier>  
1094 | element. The EncodingType attribute SHOULD be set to #Base64Binary. Other encoding  
1095 | types MAY be specified if agreed on by all parties. The ~~wsse11:TokenType~~ attribute MUST be  
1096 | set to

1097 | http://docs.oasis-open.org/wss/2005/xx/oasis-2005xx-wss-soap-message-  
1098 | security-1.1#EncryptedKey. The identifier for a <xenc:EncryptedKey> token is defined  
1099 | as the SHA1 of the raw (pre-base64 encoding) octets specified in the <xenc:CipherValue>  
1100 | element of the referenced <xenc:EncryptedKey> token. This value is encoded as indicated in  
1101 | the KeyIdentifier reference. The ~~wsse:ValueType~~ attribute of <wsse:KeyIdentifier>  
1102 | MUST be set to http://docs.oasis-open.org/wss/2005/xx/oasis-2005xx-wss-

1143 As well, the following table outlines additional algorithms that MAY be used:  
1144

Algorithm Type	Algorithm	Algorithm URI
Transform	SOAP Message Normalization	http://www.w3.org/TR/soap12-n11n/

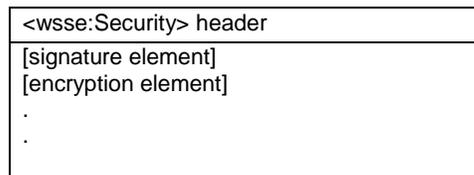

1145  
1146 The Exclusive XML Canonicalization algorithm addresses the pitfalls of general canonicalization  
1147 that can occur from *leaky* namespaces with pre-existing signatures.

1148  
1149 Finally, if a producer wishes to sign a message before encryption, then following the ordering  
1150 rules laid out in section 5, "Security Header", they SHOULD first prepend the signature element to  
1151 the `<wsse:Security>` header, and then prepend the encryption element, resulting in a  
1152 `<wsse:Security>` header that has the encryption element first, followed by the signature  
1153 element:  
1154

Formatted: Left  
Formatted: Left, Line spacing: single  
Formatted: Left

1155  
1156 Likewise, if a producer wishes to sign a message after encryption, they SHOULD first prepend  
1157 the encryption element to the `<wsse:Security>` header, and then prepend the signature  
1158 element. This will result in a `<wsse:Security>` header that has the signature element first,  
1159 followed by the encryption element:  
1160

Formatted: Left  
Formatted: Left, Line spacing: single  
Formatted: Left

1161  
1162 The XML Digital Signature WG has defined two canonicalization algorithms: XML  
1163 Canonicalization and Exclusive XML Canonicalization. To prevent confusion, the first is also  
1164 called Inclusive Canonicalization. Neither one solves all possible problems that can arise. The  
1165 following informal discussion is intended to provide guidance on the choice of which one to use  
1166 in particular circumstances. For a more detailed and technically precise discussion of these  
1167 issues see: [XML-C14N] and [EXC-C14N].  
1168

1169 There are two problems to be avoided. On the one hand, XML allows documents to be changed  
1170 in various ways and still be considered equivalent. For example, duplicate namespace  
1171 declarations can be removed or created. As a result, XML tools make these kinds of changes  
1172 freely when processing XML. Therefore, it is vital that these equivalent forms match the same  
1173 signature.

Deleted: 28  
Deleted: June

1174

1175 On the other hand, if the signature simply covers something like `xx:foo`, its meaning may change  
1176 if `xx` is redefined. In this case the signature does not prevent tampering. It might be thought that  
1177 the problem could be solved by expanding all the values in line. Unfortunately, there are  
1178 mechanisms like XPATH which consider `xx="http://example.com/"`; to be different from  
1179 `yy="http://example.com/"`; even though both `xx` and `yy` are bound to the same namespace.  
1180 The fundamental difference between the Inclusive and Exclusive Canonicalization is the  
1181 namespace declarations which are placed in the output. Inclusive Canonicalization copies all the  
1182 declarations that are currently in force, even if they are defined outside of the scope of the  
1183 signature. It also copies any `xml:` attributes that are in force, such as `xml:lang` or `xml:base`.  
1184 This guarantees that all the declarations you might make use of will be unambiguously specified.  
1185 The problem with this is that if the signed XML is moved into another XML document which has  
1186 other declarations, the Inclusive Canonicalization will copy them and the signature will be invalid.  
1187 This can even happen if you simply add an attribute in a different namespace to the surrounding  
1188 context.

1189

1190 Exclusive Canonicalization tries to figure out what namespaces you are actually using and just  
1191 copies those. Specifically, it copies the ones that are "visibly used", which means the ones that  
1192 are a part of the XML syntax. However, it does not look into attribute values or element content,  
1193 so the namespace declarations required to process these are not copied. For example  
1194 if you had an attribute like `xx:foo="yy:bar"` it would copy the declaration for `xx`, but not `yy`. (This  
1195 can even happen without your knowledge because XML processing tools **might** add `xsi:type` if  
1196 you use a schema subtype.) It also does not copy the `xml:` attributes that are declared outside the  
1197 scope of the signature.

Deleted: will

1198

1199 Exclusive Canonicalization allows you to create a list of the namespaces that must be declared,  
1200 so that it will pick up the declarations for the ones that are not visibly used. The only problem is  
1201 that the software doing the signing must know what they are. In a typical SOAP software  
1202 environment, the security code will typically be unaware of all the namespaces being used by the  
1203 application in the message body that it is signing.

1204

1205 Exclusive Canonicalization is useful when you have a signed XML document that you wish to  
1206 insert into other XML documents. A good example is a signed SAML assertion which might be  
1207 inserted as a XML Token in the security header of various SOAP messages. The Issuer who  
1208 signs the assertion will be aware of the namespaces being used and able to construct the list.  
1209 The use of Exclusive Canonicalization will insure the signature verifies correctly every time.  
1210 Inclusive Canonicalization is useful in the typical case of signing part or all of the SOAP body in  
1211 accordance with this specification. This will insure all the declarations fall under the signature,  
1212 even though the code is unaware of what namespaces are being used. At the same time, it is  
1213 less likely that the signed data (and signature element) will be inserted in some other XML  
1214 document. Even if this is desired, it still may not be feasible for other reasons, for example there  
1215 may be `Id`'s with the same value defined in both XML documents.

1216

1217 In other situations it will be necessary to study the requirements of the application and the  
1218 detailed operation of the canonicalization methods to determine which is appropriate.  
1219 This section is non-normative.

1220

## 8.2 Signing Messages

1221

The <wsse:Security> header block MAY be used to carry a signature compliant with the XML Signature specification within a SOAP Envelope for the purpose of signing one or more elements in the SOAP Envelope. Multiple signature entries MAY be added into a single SOAP Envelope within one <wsse:Security> header block. Producers SHOULD sign all important elements of the message, and careful thought must be given to creating a signing policy that requires signing of parts of the message that might legitimately be altered in transit.

1222

1223

1224

1225

1226

1227

SOAP applications MUST satisfy the following conditions:

1228

1229

1230

1231

1232

1233

1234

1235

1236

1237

1238

1239

1240

1241

1242

1243

1244

1245

1246

1247

1248

1249

1250

1251

1252

- A compliant implementation MUST be capable of processing the required elements defined in the XML Signature specification.
- To add a signature to a <wsse:Security> header block, a <ds:Signature> element conforming to the XML Signature specification MUST be prepended to the existing content of the <wsse:Security> header block, in order to indicate to the receiver the correct order of operations. All the <ds:Reference> elements contained in the signature SHOULD refer to a resource within the enclosing SOAP envelope as described in the XML Signature specification. However, since the SOAP message exchange model allows intermediate applications to modify the Envelope (add or delete a header block; for example), XPath filtering does not always result in the same objects after message delivery. Care should be taken in using XPath filtering so that there is no unintentional validation failure due to such modifications.
- The problem of modification by intermediaries (especially active ones) is applicable to more than just XPath processing. Digital signatures, because of canonicalization and digests, present particularly fragile examples of such relationships. If overall message processing is to remain robust, intermediaries must exercise care that the transformation algorithms used do not affect the validity of a digitally signed component.
- Due to security concerns with namespaces, this specification strongly RECOMMENDS the use of the "Exclusive XML Canonicalization" algorithm or another canonicalization algorithm that provides equivalent or greater protection.
- For processing efficiency it is RECOMMENDED to have the signature added and then the security token pre-pended so that a processor can read and cache the token before it is used.

1253

## 8.3 Signing Tokens

1254

It is often desirable to sign security tokens that are included in a message or even external to the message. The XML Signature specification provides several common ways for referencing information to be signed such as URIs, IDs, and XPath, but some token formats may not allow tokens to be referenced using URIs or IDs and XPaths may be undesirable in some situations. This specification allows different tokens to have their own unique reference mechanisms which are specified in their profile as extensions to the <wsse:SecurityTokenReference> element. This element provides a uniform referencing mechanism that is guaranteed to work with all token formats. Consequently, this specification defines a new reference option for XML Signature: the STR Dereference Transform.

1255

1264 | This transform is specified by the URI #STR-Transform, and when applied to a  
1265 <wsse:SecurityTokenReference> element it means that the output is the token referenced  
1266 by the <wsse:SecurityTokenReference> element not the element itself.

Deleted: (Note that URI fragments are relative to this document's URI)

1267  
1268 As an overview the processing model is to echo the input to the transform except when a  
1269 <wsse:SecurityTokenReference> element is encountered. When one is found, the element  
1270 is not echoed, but instead, it is used to locate the token(s) matching the criteria and rules defined  
1271 by the <wsse:SecurityTokenReference> element and echo it (them) to the output.  
1272 Consequently, the output of the transformation is the resultant sequence representing the input  
1273 with any <wsse:SecurityTokenReference> elements replaced by the referenced security  
1274 token(s) matched.

1275  
1276 The following illustrates an example of this transformation which references a token contained  
1277 within the message envelope:

```
1278 ...  
1279 <wsse:SecurityTokenReference wsu:Id="Str1">  
1280   ...  
1281 </wsse:SecurityTokenReference>  
1282 ...  
1283 <ds:Signature xmlns:ds="http://www.w3.org/2000/09/xmldsig#">  
1284   <ds:SignedInfo>  
1285     ...  
1286     <ds:Reference URI="#Str1">  
1287       <ds:Transforms>  
1288         <ds:Transform  
1289           Algorithm="...#STR-Transform">  
1290             <wsse:TransformationParameters>  
1291               <ds:CanonicalizationMethod  
1292                 Algorithm="http://www.w3.org/TR/2001/REC-xml-  
1293 c14n-20010315" />  
1294             </wsse:TransformationParameters>  
1295           </ds:Transform>  
1296           <ds:DigestMethod Algorithm=  
1297             "http://www.w3.org/2000/09/xmldsig#sha1" />  
1298             <ds:DigestValue>...</ds:DigestValue>  
1299           </ds:Reference>  
1300         </ds:SignedInfo>  
1301         <ds:SignatureValue></ds:SignatureValue>  
1302       </ds:Signature>  
1303     ...  
1304   ...  
1305
```

1306 The following describes the attributes and elements listed in the example above:

1307 /wsse:TransformationParameters

1308 This element is used to wrap parameters for a transformation allows elements even from  
1309 the XML Signature namespace.

1310 /wsse:TransformationParameters/ds:Canonicalization

1311 This specifies the canonicalization algorithm to apply to the selected data.

Deleted: canonicalization

1312 /wsse:TransformationParameters/{any}

Deleted: 28

Deleted: June

1316 | This is an extensibility mechanism to allow different (extensible) parameters to be  
1317 | specified in the future. Unrecognized parameters SHOULD cause a fault.  
1318 |  
1319 | */wsse:TransformationParameters/@{any}*  
1320 | This is an extensibility mechanism to allow additional attributes, based on schemas, to be  
1321 | added to the element in the future. Unrecognized attributes SHOULD cause a fault.  
1322 |  
1323 | The following is a detailed specification of the transformation. The algorithm is identified by the  
1324 | URI: #STR-Transform.  
1325 |  
1326 | Transform Input:  
1327 | • The input is a node set. If the input is an octet stream, then it is automatically parsed; cf.  
1328 | XML Digital Signature [XMLSIG].  
1329 | Transform Output:  
1330 | • The output is an octet stream.  
1331 | Syntax:  
1332 | • The transform takes a single mandatory parameter, a  
1333 | <ds:CanonicalizationMethod> element, which is used to serialize the input node  
1334 | set. Note, however, that the output may not be strictly in canonical form, per the  
1335 | canonicalization algorithm; however, the output is canonical, in the sense that it is  
1336 | unambiguous. However, because of syntax requirements in the XML Signature  
1337 | definition, this parameter MUST be wrapped in a  
1338 | <wsse:TransformationParameters> element.  
1339 | •  
1340 | Processing Rules:  
1341 | • Let N be the input node set.  
1342 | • Let R be the set of all <wsse:SecurityTokenReference> elements in N.  
1343 | • For each Ri in R, let Di be the result of dereferencing Ri.  
1344 | • If Di cannot be determined, then the transform MUST signal a failure.  
1345 | • If Di is an XML security token (e.g., a SAML assertion or a  
1346 | <wsse:BinarySecurityToken> element), then let Ri' be Di. Otherwise, Di is a raw  
1347 | binary security token; i.e., an octet stream. In this case, let Ri' be a node set consisting of  
1348 | a <wsse:BinarySecurityToken> element, utilizing the same namespace prefix as  
1349 | the <wsse:SecurityTokenReference> element Ri, with no EncodingType attribute,  
1350 | a ValueType attribute identifying the content of the security token, and text content  
1351 | consisting of the binary-encoded security token, with no white space.  
1352 | • Finally, employ the canonicalization method specified as a parameter to the transform to  
1353 | serialize N to produce the octet stream output of this transform; but, in place of any  
1354 | dereferenced <wsse:SecurityTokenReference> element Ri and its descendants,  
1355 | process the dereferenced node set Ri' instead. During this step, canonicalization of the  
1356 | replacement node set MUST be augmented as follows:  
1357 | o Note: A namespace declaration xmlns="" MUST be emitted with every apex  
1358 | element that has no namespace node declaring a value for the default  
1359 | namespace; cf. XML Decryption Transform.  
1360 |  
1361 | Signing a SecurityTokenReference (STR) provides authentication and integrity protection  
1362 | of only the STR and not the referenced security token (ST). If signing the ST is the  
1363 | intended behavior, the STR Dereference Transform (STRDT) may be used which  
1364 | replaces the STR with the ST for digest computation, effectively protecting the ST and

Deleted: 28

1370

## 8.4 Signature Validation

1371  
1372  
1373  
1374  
1375  
1376  
1377  
1378  
1379  
1380  
1381  
1382  
1383  
1384

The validation of a `<ds:Signature>` element inside an `<wsse:Security>` header block **MUST** fail if:

- the syntax of the content of the element does not conform to this specification, or
- the validation of the signature contained in the element fails according to the core validation of the XML Signature specification [XMLSIG], or
- the application applying its own validation policy rejects the message for some reason (e.g., the signature is created by an untrusted key – verifying the previous two steps only performs cryptographic validation of the signature).

If the validation of the signature element fails, applications MAY report the failure to the producer using the fault codes defined in Section 12 Error Handling.

The signature validation shall additionally adhere to the rules defines in signature confirmation section below, if the initiator desires signature confirmation:

1385

## 8.5 Signature Confirmation

1386  
1387  
1388  
1389  
1390  
1391  
1392  
1393  
1394  
1395  
1396  
1397  
1398  
1399  
1400  
1401

In the general model, the initiator uses XML Signature constructs to represent message parts of the request that were signed. The manifest of signed SOAP elements is contained in the `<ds:Signature>` element which in turn is placed inside the `<wsse:Security>` header. The `<ds:Signature>` element of the request contains a `<ds:SignatureValue>`. This element contains a base64 encoded value representing the actual digital signature. In certain situations it is desirable that initiator confirms that the message received was generated in response to a message it initiated in its unaltered form. This helps prevent certain forms of attack. This specification introduces a `<wsse11:SignatureConfirmation>` element to address this necessity.

Compliant responder implementations that support signature confirmation, **MUST** include a `<wsse11:SignatureConfirmation>` element inside the `<wsse:Security>` header of the associated response message for every `<ds:Signature>` element that is a direct child of the `<wsse:Security>` header block in the originating message. The responder **MUST** include the contents of the `<ds:SignatureValue>` element of the request signature as the value of the `@Value` attribute of the `<wsse11:SignatureConfirmation>` element. The

Deleted: 28  
Deleted: June

1402 <wssell:SignatureConfirmation> element MUST be included in the message signature of  
1403 the associated response message.

1404

1405 If the associated originating signature is received in encrypted form then the corresponding  
1406 <wssell:SignatureConfirmation> element SHOULD be encrypted to protect the original  
1407 signature and keys.

1408

1409 The schema outline for this element is as follows:

```
1410 <wssell:SignatureConfirmation wsu:Id="..." Value="..." />
```

1411 /wsse11:SignatureConfirmation

1412 This element indicates that the responder has processed the signature in the request.  
1413 When this element is not present in a response the initiator SHOULD interpret that the  
1414 responder is not compliant with this functionality.

1415

1416 /wsse11:SignatureConfirmation/@wsu:Id

1417 Identifier to be used when referencing this element in the SignedInfo reference list of the  
1418 signature of the associated response message. This attribute MUST be present so that  
1419 un-ambiguous references can be made to this <wssell:SignatureConfirmation>  
1420 element.

1421

1422 /wsse11:SignatureConfirmation/@Value

1423 This optional attribute contains the contents of a <ds:SignatureValue> copied from  
1424 the associated request. If the request was not signed, then this attribute MUST NOT be  
1425 present. If this attribute is specified with an empty value, the initiator SHOULD interpret  
1426 this as incorrect behavior and process accordingly. When this attribute is not present, the  
1427 initiator SHOULD interpret this to mean that the response is based on a request that was  
1428 not signed.

## 1429 8.5.1 Response Generation Rules

1430 ~~Conformant responders MUST include at least one <wssell:SignatureConfirmation>~~  
1431 ~~element in the <wsse:Security> header in any response(s) associated with requests. That is,~~  
1432 ~~the normal messaging patterns are not altered.~~

1433 For every response message generated, the responder MUST include a  
1434 <wssell:SignatureConfirmation> element for every <ds:Signature> element it  
1435 processed from the original request message. The Value attribute MUST be set to the exact  
1436 value of the <ds:SignatureValue> element of the corresponding <ds:Signature> element.  
1437 If no <ds:Signature> elements are present in the original request message, the responder  
1438 MUST include exactly one <wssell:SignatureConfirmation> element. The Value attribute  
1439 of the <wssell:SignatureConfirmation> element MUST NOT be present. The responder  
1440 MUST include all <wssell:SignatureConfirmation> elements in the message signature of  
1441 the response message(s). If the <ds:Signature> element corresponding to a  
1442 <wssell:SignatureConfirmation> element was encrypted in the original request message,  
1443 the <wssell:SignatureConfirmation> element SHOULD be encrypted for the recipient of  
1444 the response message(s).

1445

**Deleted:** If the responder does not comply with this specification, it MUST NOT include any <wssell:SignatureConfirmation> elements in response messages it generates

**Deleted:** If

**Formatted:** Text Char1,t Char,t Char1, Font: (Default) Helvetica, Font color: Auto, (Asian) Japanese

**Deleted:** the responder complies with this specification, it MUST include at least one <wssell:SignatureConfirmation>

**Deleted:** 28

**Deleted:** June

1446 **8.5.2 Response Processing Rules**

1447 The signature validation shall additionally adhere to the following processing guidelines, if the  
1448 initiator desires signature confirmation:

- 1449 • If a response message does not contain a <wssell:SignatureConfirmation>  
1450 element inside the <wsse:Security> header, the initiator SHOULD reject the response  
1451 message.
- 1452 • If a response message does contain a <wssell:SignatureConfirmation> element  
1453 inside the <wsse:Security> header but @Value attribute is not present on  
1454 <wssell:SignatureConfirmation> element, and the associated request message  
1455 did include a <ds:Signature> element, the initiator SHOULD reject the response  
1456 message.
- 1457 • If a response message does contain a <wssell:SignatureConfirmation> element  
1458 inside the <wsse:Security> header and the @Value attribute is present on the  
1459 <wssell:SignatureConfirmation> element, but the associated request did not  
1460 include a <ds:Signature> element, the initiator SHOULD reject the response  
1461 message.
- 1462 • If a response message does contain a <wssell:SignatureConfirmation> element  
1463 inside the <wsse:Security> header, and the associated request message did include  
1464 a <ds:Signature> element and the @Value attribute is present but does not match the  
1465 stored signature value of the associated request message, the initiator SHOULD reject  
1466 the response message.
- 1467 • If a response message does not contain a <wssell:SignatureConfirmation>  
1468 element inside the <wsse:Security> header corresponding to each  
1469 <ds:Signature> element or if the @Value attribute present does not match the stored  
1470 signature values of the associated request message, the initiator SHOULD reject the  
1471 response message.

1520

## 9 Encryption

1521 | This specification allows encryption of any combination of body blocks, header blocks, and any of  
1522 | these sub-structures by either a common symmetric key shared by the producer and the recipient  
1523 | or a symmetric key carried in the message in an encrypted form.

1524

1525 | In order to allow this flexibility, this specification leverages the XML Encryption standard. This  
1526 | specification describes how the two elements `<xenc:ReferenceList>` and  
1527 | `<xenc:EncryptedKey>` listed below and defined in XML Encryption can be used within the  
1528 | `<wsse:Security>` header block. When a producer or an active intermediary encrypts  
1529 | portion(s) of a SOAP message using XML Encryption it MUST prepend a sub-element to the  
1530 | `<wsse:Security>` header block. Furthermore, the encrypting party MUST either prepend the  
1531 | sub-element to an existing `<wsse:Security>` header block for the intended recipients or create  
1532 | a new `<wsse:Security>` header block and insert the sub-element. The combined process of  
1533 | encrypting portion(s) of a message and adding one of these sub-elements is called an encryption  
1534 | step hereafter. The sub-element MUST contain the information necessary for the recipient to  
1535 | identify the portions of the message that it is able to decrypt.

1536

1537 | This specification additionally defines an element `<wsse11:EncryptedHeader>` for containing  
1538 | encrypted SOAP header blocks. This specification RECOMMENDS an additional mechanism that  
1539 | uses this element for encrypting SOAP header blocks that complies with SOAP processing  
1540 | guidelines while preserving the confidentiality of attributes on the SOAP header blocks.  
1541 | All compliant implementations MUST be able to support the XML Encryption standard [XMLENC].

1542

### 9.1 xenc:ReferenceList

1543 | The `<xenc:ReferenceList>` element from XML Encryption [XMLENC] MAY be used to  
1544 | create a manifest of encrypted portion(s), which are expressed as `<xenc:EncryptedData>`  
1545 | elements within the envelope. An element or element content to be encrypted by this encryption  
1546 | step MUST be replaced by a corresponding `<xenc:EncryptedData>` according to XML  
1547 | Encryption. All the `<xenc:EncryptedData>` elements created by this encryption step  
1548 | SHOULD be listed in `<xenc:DataReference>` elements inside one or more  
1549 | `<xenc:ReferenceList>` element.

1550

1551 | Although in XML Encryption [XMLENC], `<xenc:ReferenceList>` was originally designed to  
1552 | be used within an `<xenc:EncryptedKey>` element (which implies that all the referenced  
1553 | `<xenc:EncryptedData>` elements are encrypted by the same key), this specification allows  
1554 | that `<xenc:EncryptedData>` elements referenced by the same `<xenc:ReferenceList>`  
1555 | MAY be encrypted by different keys. Each encryption key can be specified in `<ds:KeyInfo>`  
1556 | within individual `<xenc:EncryptedData>`.

1557

1558 | A typical situation where the `<xenc:ReferenceList>` sub-element is useful is that the  
1559 | producer and the recipient use a shared secret key. The following illustrates the use of this sub-  
1560 | element:

1561

1577         <xenc:CipherValue>...</xenc:CipherValue>
1578       </xenc:CipherData>
1579     </xenc:EncryptedData>
1580   </S11:Body>
1581 </S11:Envelope>

```

## 9.2 xenc:EncryptedKey

1583 When the encryption step involves encrypting elements or element contents within a SOAP  
 1584 envelope with a symmetric key, which is in turn to be encrypted by the recipient's key and  
 1585 embedded in the message, <xenc:EncryptedKey> MAY be used for carrying such an  
 1586 encrypted key. This sub-element MAY contain a manifest, that is, an <xenc:ReferenceList>  
 1587 element, that lists the portions to be decrypted with this key. The manifest MAY appear outside  
 1588 the <xenc:EncryptedKey provided that the corresponding <xenc:EncryptedData  
 1589 elements contain <xenc:KeyInfo elements that reference the EncryptedKey. An element or  
 1590 element content to be encrypted by this encryption step MUST be replaced by a corresponding  
 1591 <xenc:EncryptedData> according to XML Encryption. All the <xenc:EncryptedData>  
 1592 elements created by this encryption step SHOULD be listed in the <xenc:ReferenceList>  
 1593 element inside this sub-element.

1594 This construct is useful when encryption is done by a randomly generated symmetric key that is  
 1595 in turn encrypted by the recipient's public key. The following illustrates the use of this element:

```

1597 <S11:Envelope xmlns:S11="..." xmlns:wsse="..." xmlns:wsu="..."
1598 xmlns:ds="..." xmlns:xenc="...">
1599   <S11:Header>
1600     <wsse:Security>
1601       <xenc:EncryptedKey>
1602         ...
1603         <ds:KeyInfo>
1604           <wsse:SecurityTokenReference>
1605             <ds:X509IssuerSerial>
1606               <ds:X509IssuerName>
1607                 DC=ACMECorp, DC=com
1608               </ds:X509IssuerName>
1609             <ds:X509SerialNumber>12345678</ds:X509SerialNumber>
1610             </ds:X509IssuerSerial>
1611           </wsse:SecurityTokenReference>
1612         </ds:KeyInfo>
1613       </xenc:EncryptedKey>
1614     </wsse:Security>
1615   </S11:Header>
1616   <S11:Body>
1617     ...
1618   </S11:Body>
1619 </S11:Envelope>

1625  
1626  
1627

```
        </ds:KeyInfo>
        ...
        </xenc:EncryptedKey>
    ...
    </wsse:Security>
</S11:Header>
<S11:Body>
  <xenc:EncryptedData Id="bodyID">
    <xenc:CipherData>
      <xenc:CipherValue>...</xenc:CipherValue>
    </xenc:CipherData>
  </xenc:EncryptedData>
</S11:Body>
</S11:Envelope>
```

1628 While XML Encryption specifies that `<xenc:EncryptedKey>` elements MAY be specified in  
1629 `<xenc:EncryptedData>` elements, this specification strongly RECOMMENDS that  
1630 `<xenc:EncryptedKey>` elements be placed in the `<wsse:Security>` header.

### 1631 9.3 Encrypted Header

1632 In order to be compliant with SOAP mustUnderstand processing guidelines and to prevent  
1633 disclosure of information contained in attributes on a SOAP header block, this specification  
1634 introduces an `<wsse11:EncryptedHeader>` element. This element contains exactly one  
1635 `<xenc:EncryptedData>` element. This specification RECOMMENDS the use of  
1636 `<wsse11:EncryptedHeader>` element for encrypting SOAP header blocks.

### 1637 9.4 Processing Rules

1638 Encrypted parts or using one of the sub-elements defined above MUST be in compliance with the  
1639 XML Encryption specification. An encrypted SOAP envelope MUST still be a valid SOAP  
1640 envelope. The message creator MUST NOT encrypt the `<S11:Header>`, `<S12:Header>`,  
1641 `<S11:Envelope>`, `<S12:Envelope>`, or `<S11:Body>`, `<S12:Body>` elements but MAY  
1642 encrypt child elements of either the `<S11:Header>`, `<S12:Header>` and `<S11:Body>` or  
1643 `<S12:Body>` elements. Multiple steps of encryption MAY be added into a single  
1644 `<wsse:Security>` header block if they are targeted for the same recipient.

Formatted: Font: Courier New

1645  
1646 When an element or element content inside a SOAP envelope (e.g. the contents of the  
1647 `<S11:Body>` or `<S12:Body>` elements) are to be encrypted, it MUST be replaced by an  
1648 `<xenc:EncryptedData>`, according to XML Encryption and it SHOULD be referenced from the  
1649 `<xenc:ReferenceList>` element created by this encryption step. If the target of reference is  
1650 an `EncryptedHeader` as defined in section 9.3 above, see processing rules defined in section  
1651 9.5.3 Encryption using EncryptedHeader and section 9.5.4 Decryption of EncryptedHeader  
1652 below.

Formatted: Font: Courier New

#### 1653 9.4.1 Encryption

1654 The general steps (non-normative) for creating an encrypted SOAP message in compliance with  
1655 this specification are listed below (note that use of `<xenc:ReferenceList>` is  
1656 RECOMMENDED. Additionally, if the target of encryption is a SOAP header, processing rules  
1657 defined in section 9.5.3 SHOULD be used).

Deleted: 28

Deleted: June

1658 | Create a new SOAP envelope.  
1659 | Create a `<wsse:Security>` header  
1660 | When an `<xenc:EncryptedKey>` is used, create a `<xenc:EncryptedKey>` sub-element of  
1661 | the `<wsse:Security>` element. This `<xenc:EncryptedKey>` sub-element SHOULD contain  
1662 | an `<xenc:ReferenceList>` sub-element, containing a `<xenc:DataReference>` to each  
1663 | `<xenc:EncryptedData>` element that was encrypted using that key.  
1664 | Locate data items to be encrypted, i.e., XML elements, element contents within the target SOAP  
1665 | envelope.  
1666 | Encrypt the data items as follows: For each XML element or element content within the target  
1667 | SOAP envelope, encrypt it according to the processing rules of the XML Encryption specification  
1668 | [XMLENC]. Each selected original element or element content MUST be removed and replaced  
1669 | by the resulting `<xenc:EncryptedData>` element.  
1670 | The optional `<ds:KeyInfo>` element in the `<xenc:EncryptedData>` element MAY reference  
1671 | another `<ds:KeyInfo>` element. Note that if the encryption is based on an attached security  
1672 | token, then a `<wsse:SecurityTokenReference>` element SHOULD be added to the  
1673 | `<ds:KeyInfo>` element to facilitate locating it.  
1674 | Create an `<xenc:DataReference>` element referencing the generated  
1675 | `<xenc:EncryptedData>` elements. Add the created `<xenc:DataReference>` element to the  
1676 | `<xenc:ReferenceList>`.  
1677 | Copy all non-encrypted data.

Formatted: No bullets or numbering

## 1678 | 9.4.2 Decryption

1679 | On receiving a SOAP envelope containing encryption header elements, for each encryption  
1680 | header element the following general steps should be processed (this section is non-normative.  
1681 | Additionally, if the target of reference is an `EncryptedHeader`, processing rules as defined in  
1682 | section 9.5.4 below SHOULD be used):

- 1683 | 1. Identify any decryption keys that are in the recipient's possession, then identifying any  
1684 | message elements that it is able to decrypt.
- 1685 | 2. Locate the `<xenc:EncryptedData>` items to be decrypted (possibly using the  
1686 | `<xenc:ReferenceList>`).
- 1687 | 3. Decrypt them as follows:
  - 1688 | a. For each element in the target SOAP envelope, decrypt it according to the  
1689 | processing rules of the XML Encryption specification and the processing rules  
1690 | listed above.
  - 1691 | b. If the decryption fails for some reason, applications MAY report the failure to the  
1692 | producer using the fault code defined in Section 12 Error Handling of this  
1693 | specification.
  - 1694 | c. It is possible for overlapping portions of the SOAP message to be encrypted in  
1695 | such a way that they are intended to be decrypted by SOAP nodes acting in  
1696 | different Roles. In this case, the `<xenc:ReferenceList>` or  
1697 | `<xenc:EncryptedKey>` elements identifying these encryption operations will  
1698 | necessarily appear in different `<wsse:Security>` headers. Since SOAP does  
1699 | not provide any means of specifying the order in which different Roles will  
1700 | process their respective headers, this order is not specified by this specification  
1701 | and can only be determined by a prior agreement.

Deleted: 28

Deleted: June

### 1703 9.4.3 Encryption with EncryptedHeader

1704 When it is required that an entire SOAP header block including the top-level element and its  
1705 attributes be encrypted, the original header block SHOULD be replaced with a  
1706 <wsse11:EncryptedHeader> element. The <wsse11:EncryptedHeader> element MUST contain  
1707 the <xenc:EncryptedData> produced by encrypting the header block. A wsu:Id attribute MAY be  
1708 added to the <wsse11:EncryptedHeader> element for referencing. If the referencing  
1709 <wsse:Security> header block defines a value for the <S12:mustUnderstand> or  
1710 <S11:mustUnderstand> attribute, that attribute and associated value MUST be copied to the  
1711 <wsse11:EncryptedHeader> element. If the referencing <wsse:Security> header block defines a  
1712 value for the S12:role or S11:actor attribute, that attribute and associated value MUST be copied  
1713 to the <wsse11:EncryptedHeader> element. If the referencing <wsse:Security> header block  
1714 defines a value for the S12:relay attribute, that attribute and associated value MUST be copied  
1715 to the <wsse11:EncryptedHeader> element.

1716  
1717 Any header block can be replaced with a corresponding <wsse11:EncryptedHeader> header  
1718 block. This includes <wsse:Security> header blocks. (In this case, obviously if the encryption  
1719 operation is specified in the same security header or in a security header targeted at a node  
1720 which is reached after the node targeted by the <wsse11:EncryptedHeader> element, the  
1721 decryption will not occur.)

1722  
1723 In addition, <wsse11:EncryptedHeader> header blocks can be super-encrypted and replaced  
1724 by other <wsse11:EncryptedHeader> header blocks (for wrapping/tunneling scenarios). Any  
1725 <wsse:Security> header that encrypts a header block targeted to a particular actor SHOULD  
1726 be targeted to that same actor, unless it is a security header.

### 1727 9.4.4 Processing an EncryptedHeader

1728 The processing model for <wsse11:EncryptedHeader> header blocks is as follows:

- 1729 1. Resolve references to encrypted data specified in the <wsse:Security> header block  
1730 targeted at this node. For each reference, perform the following steps.
- 1731 2. If the referenced element does not have a qualified name of  
1732 <wsse11:EncryptedHeader> then process as per section 9.5.2 Decryption and stop  
1733 the processing steps here.
- 1734 3. Otherwise, extract the <xenc:EncryptedData> element from the  
1735 <wsse11:EncryptedHeader> element.
- 1736 4. Decrypt the contents of the <xenc:EncryptedData> element as per section 9.5.2  
1737 Decryption and replace the <wsse11:EncryptedHeader> element with the decrypted  
1738 contents.
- 1739 5. Process the decrypted header block as per SOAP processing guidelines.

1740

1741 Alternatively, a processor may perform a pre-pass over the encryption references in the  
1742 <wsse:Security> header:

- 1743 1. Resolve references to encrypted data specified in the <wsse:Security> header block  
1744 targeted at this node. For each reference, perform the following steps.

Deleted: 28

Deleted: June

- 1745 2. If a referenced element has a qualified name of `<wsse11:EncryptedHeader>` then  
1746 replace the `<wsse11:EncryptedHeader>` element with the contained  
1747 `<xenc:EncryptedData>` element and if present copy the value of the `wsu:Id` attribute  
1748 from the `<wsse11:EncryptedHeader>` element to the `<xenc:EncryptedData>`  
1749 element.  
1750 3. Process the `<wsse:Security>` header block as normal.

1751

1752 It should be noted that the results of decrypting a `<wsse11:EncryptedHeader>` header block  
1753 could be another `<wsse11:EncryptedHeader>` header block. In addition, the result MAY be  
1754 targeted at a different role than the role processing the `<wsse11:EncryptedHeader>` header  
1755 block.

#### 1756 9.4.5 Processing the `mustUnderstand` attribute on `EncryptedHeader`

1757 If the `S11:mustUnderstand` or `S12:mustUnderstand` attribute is specified on the  
1758 `<wsse11:EncryptedHeader>` header block, and is true, then the following steps define what it  
1759 means to "understand" the `<wsse11:EncryptedHeader>` header block:

- 1760 1. The processor MUST be aware of this element and know how to decrypt and convert into  
1761 the original header block. This DOES NOT REQUIRE that the process know that it has  
1762 the correct keys or support the indicated algorithms.
- 1763 2. The processor MUST, after decrypting the encrypted header block, process the  
1764 decrypted header block according to the SOAP processing guidelines. The receiver  
1765 MUST raise a fault if any content required to adequately process the header block  
1766 remains encrypted or if the decrypted SOAP header is not understood and the value of  
1767 the `S12:mustUnderstand` or `S11:mustUnderstand` attribute on the decrypted  
1768 header block is true. Note that in order to comply with SOAP processing rules in this  
1769 case, the processor must roll back any persistent effects of processing the security  
1770 header, such as storing a received token.

1771

1772

## 10 Security Timestamps

1773

It is often important for the recipient to be able to determine the *freshness* of security semantics.

1774

In some cases, security semantics may be so *stale* that the recipient may decide to ignore it.

1775

This specification does not provide a mechanism for synchronizing time. The assumption is that

1776

time is trusted or additional mechanisms, not described here, are employed to prevent replay.

1777

This specification defines and illustrates time references in terms of the `xsd:dateTime` type

1778

defined in XML Schema. It is RECOMMENDED that all time references use this type. ~~All~~

1779

references **MUST** be in UTC time. Implementations **MUST NOT** generate time instants that

1780

specify leap seconds. If, however, other time types are used, then the `ValueType` attribute

1781

(described below) **MUST** be specified to indicate the data type of the time format. Requestors and

1782

receivers **SHOULD NOT** rely on other applications supporting time resolution finer than

1783

milliseconds.

1784

The `<wsu:Timestamp>` element provides a mechanism for expressing the creation and

1786

expiration times of the security semantics in a message.

1787

All times **MUST** be in UTC format as specified by the XML Schema type (`dateTime`). It should be

1788

noted that times support time precision as defined in the XML Schema specification.

1789

The `<wsu:Timestamp>` element is specified as a child of the `<wsse:Security>` header and

1790

may only be present at most once per header (that is, per SOAP actor/role).

1791

The ordering within the element is as illustrated below. The ordering of elements in the

1792

`<wsu:Timestamp>` element is fixed and **MUST** be preserved by intermediaries.

1793

The schema outline for the `<wsu:Timestamp>` element is as follows:

1794

1795

1796

1797

1798

1799

1800

1801

```
<wsu:Timestamp wsu:Id="...">
  <wsu:Created ValueType="...">...</wsu:Created>
  <wsu:Expires ValueType="...">...</wsu:Expires>
  ...
</wsu:Timestamp>
```

1802

The following describes the attributes and elements listed in the schema above:

1804

*/wsu:Timestamp*

This is the element for indicating message timestamps.

1807

*/wsu:Timestamp/wsui:Created*

1808

This represents the creation time of the security semantics. This element is optional, but

1809

can only be specified once in a `<wsu:Timestamp>` element. Within the SOAP

1810

processing model, creation is the instant that the infoset is serialized for transmission.

1811

The creation time of the message **SHOULD NOT** differ substantially from its transmission

1812

time. The difference in time should be minimized.

1813

1814

*/wsu:Timestamp/wsui:Expires*

1815

Page 49 of 73

Deleted: It is further RECOMMENDED that all

Deleted: 28

Deleted: June

1816 This element represents the expiration of the security semantics. This is optional, but  
1817 can appear at most once in a <wsu:Timestamp> element. Upon expiration, the  
1818 requestor asserts that its security semantics are no longer valid. It is strongly  
1819 RECOMMENDED that recipients (anyone who processes this message) discard (ignore)  
1820 any message whose security semantics have passed their expiration. A Fault code  
1821 (wsu:MessageExpired) is provided if the recipient wants to inform the requestor that its  
1822 security semantics were expired. A service MAY issue a Fault indicating the security  
1823 semantics have expired.

1824  
1825 /wsu:Timestamp/{any}  
1826 This is an extensibility mechanism to allow additional elements to be added to the  
1827 element. Unrecognized elements SHOULD cause a fault.

1828  
1829 /wsu:Timestamp/@wsu:Id  
1830 This optional attribute specifies an XML Schema ID that can be used to reference this  
1831 element (the timestamp). This is used, for example, to reference the timestamp in a XML  
1832 Signature.

1833  
1834 /wsu:Timestamp/@{any}  
1835 This is an extensibility mechanism to allow additional attributes to be added to the  
1836 element. Unrecognized attributes SHOULD cause a fault.

1837  
1838 The expiration is relative to the requestor's clock. In order to evaluate the expiration time,  
1839 recipients need to recognize that the requestor's clock may not be synchronized to the recipient's  
1840 clock. The recipient, therefore, MUST make an assessment of the level of trust to be placed in  
1841 the requestor's clock, since the recipient is called upon to evaluate whether the expiration time is  
1842 in the past relative to the requestor's, not the recipient's, clock. The recipient may make a  
1843 judgment of the requestor's likely current clock time by means not described in this specification,  
1844 for example an out-of-band clock synchronization protocol. The recipient may also use the  
1845 creation time and the delays introduced by intermediate SOAP roles to estimate the degree of  
1846 clock skew.

1847  
1848 The following example illustrates the use of the <wsu:Timestamp> element and its content.

```
1849 <S11:Envelope xmlns:S11="..." xmlns:wsse="..." xmlns:wsu="...">  
1851 <S11:Header>  
1852 <wsse:Security>  
1853 <wsu:Timestamp wsu:Id="timestamp">  
1854 <wsu:Created>2001-09-13T08:42:00Z</wsu:Created>  
1855 <wsu:Expires>2001-10-13T09:00:00Z</wsu:Expires>  
1856 </wsu:Timestamp>  
1857 ...  
1858 </wsse:Security>  
1859 ...  
1860 </S11:Header>  
1861 <S11:Body>  
1862 ...  
1863 </S11:Body>  
1864 </S11:Envelope>
```

1865

## 11 Extended Example

1866

The following sample message illustrates the use of security tokens, signatures, and encryption.

1867

For this example, the timestamp and the message body are signed prior to encryption. The

1868

decryption transformation is not needed as the signing/encryption order is specified within the

1869

<wsse:Security> header.

1956 | <068> </S11:Envelope>

```

1957  
1958 | Let's review some of the key sections of this example:  
1959 | Lines (003)-(058) contain the SOAP message headers.

1960  
1961 | Lines (004)-(057) represent the <wsse:Security> header block. This contains the security-  
1962 | related information for the message.

1963  
1964 | Lines (005)-(008) specify the timestamp information. In this case it indicates the creation time of  
1965 | the security semantics.

1966  
1967 | Lines (010)-(012) specify a security token that is associated with the message. In this case, it  
1968 | specifies an X.509 certificate that is encoded as Base64. Line (011) specifies the actual Base64  
1969 | encoding of the certificate.

1970

Page 52 of 73

Deleted: 28  
Deleted: June

1971 | Lines (013)-(026) specify the key that is used to encrypt the body of the message. Since this is a  
1972 | symmetric key, it is passed in an encrypted form. Line (014) defines the algorithm used to  
1973 | encrypt the key. Lines (015)-(018) specify the identifier of the key that was used to encrypt the  
1974 | symmetric key. Lines (019)-(022) specify the actual encrypted form of the symmetric key. Lines  
1975 | (023)-(025) identify the encryption block in the message that uses this symmetric key. In this  
1976 | case it is only used to encrypt the body (Id="enc1").  
1977 |  
1978 | Lines (027)-(056) specify the digital signature. In this example, the signature is based on the  
1979 | X.509 certificate. Lines (028)-(047) indicate what is being signed. Specifically, line (039)  
1980 | references the message body.  
1981 |  
1982 | Lines (048)-(050) indicate the actual signature value – specified in Line (043).  
1983 |  
1984 | Lines (052)-(054) indicate the key that was used for the signature. In this case, it is the X.509  
1985 | certificate included in the message. Line (053) provides a URI link to the Lines (010)-(012).  
1986 | The body of the message is represented by Lines (059)-(067).  
1987 |  
1988 | Lines (060)-(066) represent the encrypted metadata and form of the body using XML Encryption.  
1989 | Line (060) indicates that the "element value" is being replaced and identifies this encryption. Line  
1990 | (061) specifies the encryption algorithm – Triple-DES in this case. Lines (063)-(064) contain the  
1991 | actual cipher text (i.e., the result of the encryption). Note that we don't include a reference to the  
1992 | key as the key references this encryption – Line (024).

## 12 Error Handling

There are many circumstances where an *error* can occur while processing security information. For example:

- Invalid or unsupported type of security token, signing, or encryption
- Invalid or unauthenticated or unauthenticatable security token
- Invalid signature
- Decryption failure
- Referenced security token is unavailable
- Unsupported namespace

Formatted: Bulleted + Level: 1 + Aligned at: 0" + Tab after: 0.25" + Indent at: 0.25"

If a service does not perform its normal operation because of the contents of the Security header, then that MAY be reported using SOAP's Fault Mechanism. This specification does not mandate that faults be returned as this could be used as part of a denial of service or cryptographic attack. We combine signature and encryption failures to mitigate certain types of attacks.

If a failure is returned to a producer then the failure MUST be reported using the SOAP Fault mechanism. The following tables outline the predefined security fault codes. The "unsupported" classes of errors are as follows. Note that the reason text provided below is RECOMMENDED, but alternative text MAY be provided if more descriptive or preferred by the implementation. The tables below are defined in terms of SOAP 1.1. For SOAP 1.2, the Fault/Code/Value is `env:Sender` (as defined in SOAP 1.2) and the Fault/Code/Subcode/Value is the *faultcode* below and the Fault/Reason/Text is the *faultstring* below.

Error that occurred (faultstring)	faultcode
An unsupported token was provided	wsse:UnsupportedSecurityToken
An unsupported signature or encryption algorithm was used	wsse:UnsupportedAlgorithm

## 13 Security Considerations

2021

2022

2023

2024

2025

2026

2027

As stated in the Goals and Requirements section of this document, this specification is meant to provide extensible framework and flexible syntax, with which one could implement various security mechanisms. This framework and syntax by itself *does not provide any guarantee of security*. When implementing and using this framework and syntax, one must make every effort to ensure that the result is not vulnerable to any one of a wide range of attacks.

2028

### 13.1 General Considerations

2029

2030

2031

2032

2033

It is not feasible to provide a comprehensive list of security considerations for such an extensible set of mechanisms. A complete security analysis **MUST** be conducted on specific solutions based on this specification. Below we illustrate some of the security concerns that often come up with protocols of this type, but we stress that this *is not an exhaustive list of concerns*.

2034

2035

2036

2037

2038

2039

2040

2041

2042

2043

2044

2045

2046

2047

2048

- freshness guarantee (e.g., the danger of replay, delayed messages and the danger of relying on timestamps assuming secure clock synchronization)
- proper use of digital signature and encryption (signing/encrypting critical parts of the message, interactions between signatures and encryption), i.e., signatures on (content of) encrypted messages leak information when in plain-text)
- protection of security tokens (integrity)
- certificate verification (including revocation issues)
- the danger of using passwords without utmost protection (i.e. dictionary attacks against passwords, replay, insecurity of password derived keys, ...)
- the use of randomness (or strong pseudo-randomness)
- interaction between the security mechanisms implementing this standard and other system component
- man-in-the-middle attacks
- PKI attacks (i.e. identity mix-ups)

2049

2050

2051

There are other security concerns that one may need to consider in security protocols. The list above should not be used as a "check list" instead of a comprehensive security analysis. The next section will give a few details on some of the considerations in this list.

2052

### 13.2 Additional Considerations

2053

#### 13.2.1 Replay

2054

2055

2056

2057

2058

Digital signatures alone do not provide message authentication. One can record a signed message and resend it (a replay attack). It is strongly **RECOMMENDED** that messages include digitally signed elements to allow message recipients to detect replays of the message when the messages are exchanged via an open network. These can be part of the message or of the headers defined from other SOAP extensions. Four typical approaches are: Timestamp,

WSS: SOAP Message Security (WS-Security 2004)  
Copyright © OASIS Open 2002-2005. All Rights Reserved.

11, September 2005  
Page 56 of 73

Deleted: 28

Deleted: June

2059 Sequence Number, Expirations and Message Correlation. Signed timestamps MAY be used to  
2060 keep track of messages (possibly by caching the most recent timestamp from a specific service)  
2061 and detect replays of previous messages. It is RECOMMENDED that timestamps be cached for  
2062 a given period of time, as a guideline, a value of five minutes can be used as a minimum to detect  
2063 replays, and that timestamps older than that given period of time set be rejected in interactive  
2064 scenarios.

### 2065 **13.2.2 Combining Security Mechanisms**

2066 This specification defines the use of XML Signature and XML Encryption in SOAP headers. As  
2067 one of the building blocks for securing SOAP messages, it is intended to be used in conjunction  
2068 with other security techniques. Digital signatures need to be understood in the context of other  
2069 security mechanisms and possible threats to an entity.

2070  
2071 Implementers should also be aware of all the security implications resulting from the use of digital  
2072 signatures in general and XML Signature in particular. When building trust into an application  
2073 based on a digital signature there are other technologies, such as certificate evaluation, that must  
2074 be incorporated, but these are outside the scope of this document.

2075  
2076 As described in XML Encryption, the combination of signing and encryption over a common data  
2077 item may introduce some cryptographic vulnerability. For example, encrypting digitally signed  
2078 data, while leaving the digital signature in the clear, may allow plain text guessing attacks.

### 2079 **13.2.3 Challenges**

2080 When digital signatures are used for verifying the claims pertaining to the sending entity, the  
2081 producer must demonstrate knowledge of the confirmation key. One way to achieve this is to use  
2082 a challenge-response type of protocol. Such a protocol is outside the scope of this document.  
2083 To this end, the developers can attach timestamps, expirations, and sequences to messages.

### 2084 **13.2.4 Protecting Security Tokens and Keys**

2085 Implementers should be aware of the possibility of a token substitution attack. In any situation  
2086 where a digital signature is verified by reference to a token provided in the message, which  
2087 specifies the key, it may be possible for an unscrupulous producer to later claim that a different  
2088 token, containing the same key, but different information was intended.

2089 An example of this would be a user who had multiple X.509 certificates issued relating to the  
2090 same key pair but with different attributes, constraints or reliance limits. Note that the signature of  
2091 the token by its issuing authority does not prevent this attack. Nor can an authority effectively  
2092 prevent a different authority from issuing a token over the same key if the user can prove  
2093 possession of the secret.

2094  
2095 The most straightforward counter to this attack is to insist that the token (or its unique identifying  
2096 data) be included under the signature of the producer. If the nature of the application is such that  
2097 the contents of the token are irrelevant, assuming it has been issued by a trusted authority, this  
2098 attack may be ignored. However because application semantics may change over time, best  
2099 practice is to prevent this attack.

2100 Requestors should use digital signatures to sign security tokens that do not include signatures (or  
2101 other protection mechanisms) to ensure that they have not been altered in transit. It is strongly  
2102

2103 RECOMMENDED that all relevant and immutable message content be signed by the producer.  
2104 Receivers SHOULD only consider those portions of the document that are covered by the  
2105 producer's signature as being subject to the security tokens in the message. Security tokens  
2106 appearing in <wsse:Security> header elements SHOULD be signed by their issuing authority  
2107 so that message receivers can have confidence that the security tokens have not been forged or  
2108 altered since their issuance. It is strongly RECOMMENDED that a message producer sign any  
2109 <wsse:SecurityToken> elements that it is confirming and that are not signed by their issuing  
2110 authority.  
2111 When a requester provides, within the request, a Public Key to be used to encrypt the response,  
2112 it is possible that an attacker in the middle may substitute a different Public Key, thus allowing the  
2113 attacker to read the response. The best way to prevent this attack is to bind the encryption key in  
2114 some way to the request. One simple way of doing this is to use the same key pair to sign the  
2115 request as to encrypt the response. However, if policy requires the use of distinct key pairs for  
2116 signing and encryption, then the Public Key provided in the request should be included under the  
2117 signature of the request.

### 2118 13.2.5 Protecting Timestamps and Ids

2119 In order to *trust* wsu:Id attributes and <wsu:Timestamp> elements, they SHOULD be signed  
2120 using the mechanisms outlined in this specification. This allows readers of the IDs and  
2121 timestamps information to be certain that the IDs and timestamps haven't been forged or altered  
2122 in any way. It is strongly RECOMMENDED that IDs and timestamp elements be signed.  
2123

### 2124 13.2.6 Protecting against removal and modification of XML Elements

2125 XML Signatures using Shorthand XPointer References (AKA IDREF) protect against the removal  
2126 and modification of XML elements; but do not protect the location of the element within the XML  
2127 Document.

2128 Whether or not this is a security vulnerability depends on whether the location of the signed data  
2129 within its surrounding context has any semantic import. This consideration applies to data carried  
2130 in the SOAP Body or the Header.

2131 Of particular concern is the ability to relocate signed data into a SOAP Header block which is  
2132 unknown to the receiver and marked mustUnderstand="false". This could have the effect of  
2133 causing the receiver to ignore signed data which the sender expected would either be processed  
2134 or result in the generation of a MustUnderstand fault.

2135 A similar exploit would involve relocating signed data into a SOAP Header block targeted to a  
2136 S11:actor or S12:role other than that which the sender intended, and which the receiver will not  
2137 process.

2138 While these attacks could apply to any portion of the message, their effects are most pernicious  
2139 with SOAP header elements which may not always be present, but must be processed whenever  
2140 they appear.

2141 In the general case of XML Documents and Signatures, this issue may be resolved by signing the  
2142 entire XML Document and/or strict XML Schema specification and enforcement. However,  
2143 because elements of the SOAP message, particularly header elements, may be legitimately  
2144 modified by SOAP intermediaries, this approach is usually not appropriate. It is  
2145 RECOMMENDED that applications signing any part of the SOAP body  
2146 sign the entire body.

**Deleted:** XML Signatures using Shorthand XPointer References (AKA IDREF) protect against the removal and modification of XML elements; but do not protect the location of the element within the XML Document.¶

¶ Whether or not this is security vulnerability depends on whether the location of the signed data within its surrounding context has any semantic import. This consideration applies to data carried in the SOAP Body or the Header. ¶

¶ Of particular concern is the ability to relocate signed data into a SOAP Header block which is unknown to the receiver and marked mustUnderstand="false". This could have the effect of causing the receiver to ignore signed data which the sender expected would either be processed ¶ or result in the generation of a mustUnderstand fault. ¶

¶ A similar exploit would involve relocating signed data into a SOAP Header block targeted to a S11:actor or S12:role other than that which the sender intended, and which the receiver will not process. ¶

¶ While these attacks could apply to any portion of the message, their effects are most pernicious with SOAP header elements which may not always be present, but must be processed whenever they appear. ¶

¶ In the general case of XML Documents and Signatures, this issue may be resolved by signing the entire XML Document and/or strict XML Schema specification and enforcement. 2149 modified by SOAP intermediaries, this approach is usually not appropriate. It is RECOMMENDED  
2150 that applications signing any part of the SOAP body sign the entire body.

2151  
2152 Alternatives countermeasures include (but are not limited to):

- 2153 • References using XPath transforms with Absolute Path expressions with checks  
2154 performed by the receiver that the URI and Absolute Path XPath expression evaluate to  
2155 the digested nodeset.
- 2156 • A Reference using an XPath transform to include any significant location-dependent  
2157 elements and exclude any elements that might legitimately be removed, added, or altered  
2158 by intermediaries.
- 2159 • Using only References to elements with location-independent semantics.
- 2160 • Strict policy specification and enforcement regarding which message parts are to be  
2161 signed. For example:
  - 2162 ○ Requiring that the entire SOAP Body and all children of SOAP Header be signed.
  - 2163 ○ Requiring that SOAP header elements which are marked  
2164 MustUnderstand="false" and have signed descendants MUST include the  
2165 MustUnderstand attribute under the signature.

### 2167 **13.2.7 Detecting Duplicate Identifiers**

2168 The wsse:Security processing SHOULD check for duplicate values from among the set of ID  
2169 attributes that it is aware of. The wsse:Security processing MUST generate a fault if a duplicate  
2170 ID value is detected.

## 14 Interoperability Notes

2174

Based on interoperability experiences with this and similar specifications, the following list highlights several common areas where interoperability issues have been discovered. Care should be taken when implementing to avoid these issues. It should be noted that some of these may seem "obvious", but have been problematic during testing.

2175

2176

2177

2178

2179

2180

2181

2182

2183

2184

2185

2186

2187

2188

2189

2190

2191

2192

2193

2194

2195

2196

2197

2198

2199

2200

- **Key Identifiers:** Make sure you understand the algorithm and how it is applied to security tokens.
- **EncryptedKey:** The `<xenc:EncryptedKey>` element from XML Encryption requires a `Type` attribute whose value is one of a pre-defined list of values. Ensure that a correct value is used.
- **Encryption Padding:** The XML Encryption random block cipher padding has caused issues with certain decryption implementations; be careful to follow the specifications exactly.
- **IDs:** The specification recognizes three specific ID elements: the global `wsu:Id` attribute and the local `Id` attributes on XML Signature and XML Encryption elements (because the latter two do not allow global attributes). If any other element does not allow global attributes, it cannot be directly signed using an ID reference. Note that the global attribute `wsu:Id` MUST carry the namespace specification.
- **Time Formats:** This specification uses a restricted version of the XML Schema `xsd:dateTime` element. Take care to ensure compliance with the specified restrictions.
- **Byte Order Marker (BOM):** Some implementations have problems processing the BOM marker. It is suggested that usage of this be optional.
- **SOAP, WSDL, HTTP:** Various interoperability issues have been seen with incorrect SOAP, WSDL, and HTTP semantics being applied. Care should be taken to carefully adhere to these specifications and any interoperability guidelines that are available.

## 15 Privacy Considerations

2202

In the context of this specification, we are only concerned with potential privacy violation by the security elements defined here. Privacy of the content of the payload message is out of scope.

2203

2204

Producers or sending applications should be aware that claims, as collected in security tokens, are typically personal information, and should thus only be sent according to the producer's

2205

2206

privacy policies. Future standards may allow privacy obligations or restrictions to be added to this data. Unless such standards are used, the producer must ensure by out-of-band means that the recipient is bound to adhering to all restrictions associated with the data, and the recipient must similarly ensure by out-of-band means that it has the necessary consent for its intended processing of the data.

2207

2208

2209

2210

2211

If claim data are visible to intermediaries, then the policies must also allow the release to these intermediaries. As most personal information cannot be released to arbitrary parties, this will typically require that the actors are referenced in an identifiable way; such identifiable references are also typically needed to obtain appropriate encryption keys for the intermediaries.

2212

2213

2214

2215

If intermediaries add claims, they should be guided by their privacy policies just like the original producers.

2216

2217

2218

2219

Intermediaries may also gain traffic information from a SOAP message exchange, e.g., who communicates with whom at what time. Producers that use intermediaries should verify that releasing this traffic information to the chosen intermediaries conforms to their privacy policies.

## Appendix C: Utility Elements and Attributes

2287 These specifications define several elements, attributes, and attribute groups which can be re-  
2288 used by other specifications. This appendix provides an overview of these *utility* components. It  
2289 should be noted that the detailed descriptions are provided in the specification and this appendix  
2290 will reference these sections as well as calling out other aspects not documented in the  
2291 specification.

### 2292 16.1 Identification Attribute

2293 There are many situations where elements within SOAP messages need to be referenced. For  
2294 example, when signing a SOAP message, selected elements are included in the signature. XML  
2295 Schema Part 2 provides several built-in data types that may be used for identifying and  
2296 referencing elements, but their use requires that consumers of the SOAP message either have or  
2297 are able to obtain the schemas where the identity or reference mechanisms are defined. In some  
2298 circumstances, for example, intermediaries, this can be problematic and not desirable.

2299 Consequently a mechanism is required for identifying and referencing elements, based on the  
2300 SOAP foundation, which does not rely upon complete schema knowledge of the context in which  
2301 an element is used. This functionality can be integrated into SOAP processors so that elements  
2302 can be identified and referred to without dynamic schema discovery and processing.

2303 This specification specifies a namespace-qualified global attribute for identifying an element  
2304 which can be applied to any element that either allows arbitrary attributes or specifically allows  
2305 this attribute. This is a general purpose mechanism which can be re-used as needed.  
2306 A detailed description can be found in Section 4.0 ID References.

2307 This section is non-normative.  
2308  
2309  
2310

### 2311 16.2 Timestamp Elements

2312 The specification defines XML elements which may be used to express timestamp information  
2313 such as creation and expiration. While defined in the context of message security, these  
2314 elements can be re-used wherever these sorts of time statements need to be made.

2315 The elements in this specification are defined and illustrated using time references in terms of the  
2316 *dateTime* type defined in XML Schema. It is RECOMMENDED that all time references use this  
2317 type for interoperability. It is further RECOMMENDED that all references be in UTC time for  
2318 increased interoperability. If, however, other time types are used, then the `valueType` attribute  
2319 MUST be specified to indicate the data type of the time format.

2320 The following table provides an overview of these elements:  
2321  
2322

Element	Description
<wsu:Created>	This element is used to indicate the creation time associated with the enclosing context.
<wsu:Expires>	This element is used to indicate the expiration time associated with the enclosing context.

2323  
2324 A detailed description can be found in Section 10.  
2325  
2326 This section is non-normative.  
2327

### 2328 16.3 General Schema Types

2329 The schema for the utility aspects of this specification also defines some general purpose  
2330 schema elements. While these elements are defined in this schema for use with this  
2331 specification, they are general purpose definitions that may be used by other specifications as  
2332 well.

2333  
2334 Specifically, the following schema elements are defined and can be re-used:  
2335

Schema Element	Description
wsu:commonAtts attribute group	This attribute group defines the common attributes recommended for elements. This includes the <code>wsu:Id</code> attribute as well as extensibility for other namespace qualified attributes.
wsu:AttributedDateTime type	This type extends the XML Schema <code>dateTime</code> type to include the common attributes.
wsu:AttributedURI type	This type extends the XML Schema <code>anyURI</code> type to include the common attributes.

2336  
2337 This section is non-normative.  
2338

2339

## Appendix D: SecurityTokenReference Model

2340

This appendix provides a non-normative overview of the usage and processing models for the `<wsse:SecurityTokenReference>` element.

2341

2342

2343

There are several motivations for introducing the `<wsse:SecurityTokenReference>` element:

2344

2345

2346

2347

2348

2349

2350

2351

2352

2353

2354

2355

- The XML Signature reference mechanisms are focused on "key" references rather than general token references.
- The XML Signature reference mechanisms utilize a fairly closed schema which limits the extensibility that can be applied.
- There are additional types of general reference mechanisms that are needed, but are not covered by XML Signature.
- There are scenarios where a reference may occur outside of an XML Signature and the XML Signature schema is not appropriate or desired.
- The XML Signature references may include aspects (e.g. transforms) that may not apply to all references.

2356

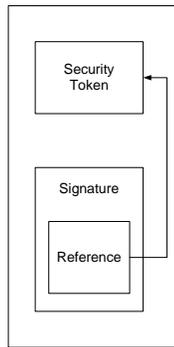

The following use cases drive the above motivations:

2357

2358

**Local Reference** – A security token, that is included in the message in the `<wsse:Security>` header, is associated with an XML Signature. The figure below illustrates this:

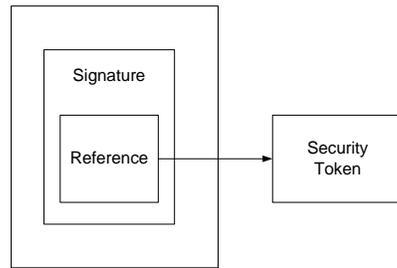

2359

2360

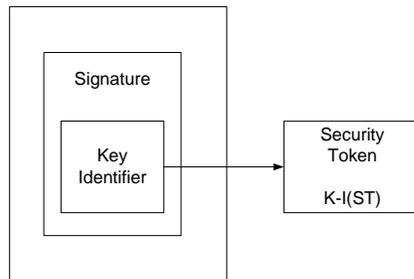

2361  
2362  
2363  
2364

**Remote Reference** – A security token, that is not included in the message but may be available at a specific URI, is associated with an XML Signature. The figure below illustrates this:

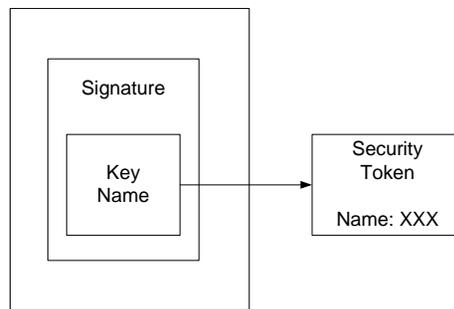

2365  
2366  
2367  
2368

**Key Identifier** – A security token, which is associated with an XML Signature and identified using a known value that is the result of a well-known function of the security token (defined by the token format or profile). The figure below illustrates this where the token is located externally:

2369  
2370  
2371  
2372

**Key Name** – A security token is associated with an XML Signature and identified using a known value that represents a "name" assertion within the security token (defined by the token format or profile). The figure below illustrates this where the token is located externally:

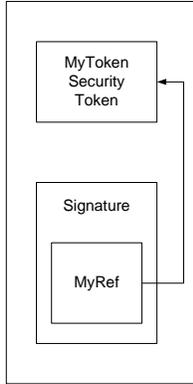

2373  
2374  
2375  
2376  
2377

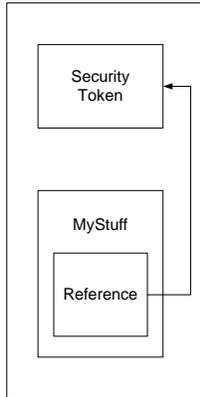

**Format-Specific References** – A security token is associated with an XML Signature and identified using a mechanism specific to the token (rather than the general mechanisms described above). The figure below illustrates this:

WSS: SOAP Message Security (WS-Security 2004)  
Copyright © OASIS Open 2002-2005. All Rights Reserved.

Deleted: 28  
Deleted: June

2378 **Non-Signature References** – A message may contain XML that does not represent an XML  
 2379 signature, but may reference a security token (which may or may not be included in the  
 2380 message). The figure below illustrates this:

2381  
 2382  
 2383 All conformant implementations **MUST** be able to process the  
 2384 `<wsse:SecurityTokenReference>` element. However, they are not required to support all of  
 2385 the different types of references.

2386  
 2387 | The reference **MAY** include a `wssell1:TokenType` attribute which provides a "hint" for the type  
 2388 of desired token.

2389  
 2390 If multiple sub-elements are specified, together they describe the reference for the token.  
 2391 There are several challenges that implementations face when trying to interoperate:  
 2392 **ID References** – The underlying XML referencing mechanism using the XML base type of ID  
 2393 provides a simple straightforward XML element reference. However, because this is an XML  
 2394 type, it can be bound to *any* attribute. Consequently in order to process the IDs and references  
 2395 requires the recipient to *understand* the schema. This may be an expensive task and in the  
 2396 general case impossible as there is no way to know the "schema location" for a specific  
 2397 namespace URI.

2398  
 2399 **Ambiguity** – The primary goal of a reference is to uniquely identify the desired token. ID  
 2400 references are, by definition, unique by XML. However, other mechanisms such as "principal  
 2401 name" are not required to be unique and therefore such references may be unique.  
 2402 The XML Signature specification defines a `<ds:KeyInfo>` element which is used to provide  
 2403 information about the "key" used in the signature. For token references within signatures, it is

 Deleted: June

2404 RECOMMENDED that the `<wsse:SecurityTokenReference>` be placed within the  
2405 `<ds:KeyInfo>`. The XML Signature specification also defines mechanisms for referencing keys  
2406 by identifier or passing specific keys. As a rule, the specific mechanisms defined in WSS: SOAP  
2407 Message Security or its profiles are preferred over the mechanisms in XML Signature.  
2408 The following provides additional details on the specific reference mechanisms defined in WSS:  
2409 SOAP Message Security:

2410  
2411 **Direct References** – The `<wsse:Reference>` element is used to provide a URI reference to  
2412 the security token. If only the fragment is specified, then it references the security token within  
2413 the document whose `wsu:Id` matches the fragment. For non-fragment URIs, the reference is to  
2414 a [potentially external] security token identified using a URI. There are no implied semantics  
2415 around the processing of the URI.

2416  
2417 **Key Identifiers** – The `<wsse:KeyIdentifier>` element is used to reference a security token  
2418 by specifying a known value (identifier) for the token, which is determined by applying a special  
2419 *function* to the security token (e.g. a hash of key fields). This approach is typically unique for the  
2420 specific security token but requires a profile or token-specific function to be specified. The  
2421 `ValueType` attribute defines the type of key identifier and, consequently, identifies the type of  
2422 token referenced. The `EncodingType` attribute specifies how the unique value (identifier) is  
2423 encoded. For example, a hash value may be encoded using base 64 encoding.

2424  
2425 **Key Names** – The `<ds:KeyName>` element is used to reference a security token by specifying a  
2426 specific value that is used to *match* an identity assertion within the security token. This is a  
2427 subset match and may result in multiple security tokens that match the specified name. While  
2428 XML Signature doesn't imply formatting semantics, WSS: SOAP Message Security  
2429 RECOMMENDS that X.509 names be specified.

2430  
2431 It is expected that, where appropriate, profiles define if and how the reference mechanisms map  
2432 to the specific token profile. Specifically, the profile should answer the following questions:

- 2433
- 2434 • What types of references can be used?
  - 2435 • How "Key Name" references map (if at all)?
  - 2436 • How "Key Identifier" references map (if at all)?
  - 2437 • Are there any additional profile or format-specific references?

2438

XML Signatures using Shorthand XPointer References (AKA IDREF) protect against the removal and modification of XML elements; but do not protect the location of the element within the XML Document.

Whether or not this is security vulnerability depends on whether the location of the signed data within its surrounding context has any semantic import. This consideration applies to data carried in the SOAP Body or the Header.

Of particular concern is the ability to relocate signed data into a SOAP Header block which is unknown to the receiver and marked `mustUnderstand="false"`. This could have the effect of causing the receiver to ignore signed data which the sender expected would either be processed or result in the generation of a `mustUnderstand` fault.

A similar exploit would involve relocating signed data into a SOAP Header block targeted to a `S11:actor` or `S12:role` other than that which the sender intended, and which the receiver will not process.

While these attacks could apply to any portion of the message, their effects are most pernicious with SOAP header elements which may not always be present, but must be processed whenever they appear.

In the general case of XML Documents and Signatures, this issue may be resolved by signing the entire XML Document and/or strict XML Schema specification and enforcement. However, because elements of the SOAP message, particularly header elements, may be legitimately modified by SOAP intermediaries, this approach is usually not appropriate. It is **RECOMMENDED** that applications signing any part of the SOAP body sign the entire body.

Alternatives countermeasures include (but are not limited to):

References using XPath transforms with Absolute Path expressions,

A Reference using an XPath transform to include any significant location-dependent elements and exclude any elements that might legitimately be removed, added, or altered by intermediaries,

Using only References to elements with location-independent semantics,

Strict policy specification and enforcement regarding which message parts are to be signed. For example:

Requiring that the entire SOAP Body and all children of SOAP Header be signed,

Requiring that SOAP header elements which are marked `mustUnderstand="false"` and have signed descendents **MUST** include the `mustUnderstand` attribute under the signature.
