Abstract:
This specification provides the definition of the atomic transaction coordination type that is to be used with the extensible coordination framework described in the WS-Coordination specification. The specification defines three specific agreement coordination protocols for the atomic transaction coordination type: completion, volatile two-phase commit, and durable two-phase commit. Developers can use any or all of these protocols when building applications that require consistent agreement on the outcome of short-lived distributed activities that have the all-or-nothing property.

Status:
This document is published by the WS-Tx TX as a “working draft”.
This document was last revised or approved by the WS-Tx TC on the above date. The level of approval is also listed above. Check the current location noted above for possible later revisions of this document. This document is updated periodically on no particular schedule.
Technical Committee members should send comments on this specification to the Technical Committee’s email list. Others should send comments to the Technical Committee by using the “Send A Comment” button on the Technical Committee’s web page at www.oasis-open.org/committees/ws-tx.

For information on whether any patents have been disclosed that may be essential to implementing this specification, and any offers of patent licensing terms, please refer to the Intellectual Property Rights section of the Technical Committee web page (www.oasis-open.org/committees/ws-tx/ipr.php).

The non-normative errata page for this specification is located at www.oasis-open.org/committees/ws-tx.
Notices

OASIS takes no position regarding the validity or scope of any intellectual property or other rights that might be claimed to pertain to the implementation or use of the technology described in this document or the extent to which any license under such rights might or might not be available; neither does it represent that it has made any effort to identify any such rights. Information on OASIS's procedures with respect to rights in OASIS specifications can be found at the OASIS website. Copies of claims of rights made available for publication and any assurances of licenses to be made available, or the result of an attempt made to obtain a general license or permission for the use of such proprietary rights by implementors or users of this specification, can be obtained from the OASIS President.

OASIS invites any interested party to bring to its attention any copyrights, patents or patent applications, or other proprietary rights which may cover technology that may be required to implement this specification. Please address the information to the OASIS President.

1 Note on terminology

The keywords "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC2119 [KEYWORDS].

Namespace URIs of the general form http://example.org and http://example.com represents some application-dependent or context-dependent URI as defined in RFC 2396 [URI].

1.1 Composable Architecture

By using the SOAP [SOAP] and WSDL [WSDL] extensibility model, SOAP-based and WSDL-based specifications are designed to work together to define a rich Web services environment. As such, WS-AtomicTransaction by itself does not define all features required for a complete solution. WS-AtomicTransaction is a building block used with other specifications of Web services (e.g., WS-Coordination, WS-Security) and application-specific protocols that are able to accommodate a wide variety of coordination protocols related to the coordination actions of distributed applications.

1.2 Namespace

The XML namespace URI that MUST be used by implementations of this specification is:

http://schemas.xmlsoap.org/ws/2004/10/wsat

This is also used as the CoordinationContext type for atomic transactions.

1.2.1 Prefix Namespace

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Namespace</th>
</tr>
</thead>
<tbody>
<tr>
<td>S</td>
<td><a href="http://www.w3.org/2003/05/soap-envelope">http://www.w3.org/2003/05/soap-envelope</a></td>
</tr>
<tr>
<td>wscoor</td>
<td><a href="http://schemas.xmlsoap.org/ws/2004/10/wscoor">http://schemas.xmlsoap.org/ws/2004/10/wscoor</a></td>
</tr>
<tr>
<td>wsat</td>
<td><a href="http://schemas.xmlsoap.org/ws/2004/10/wsat">http://schemas.xmlsoap.org/ws/2004/10/wsat</a></td>
</tr>
</tbody>
</table>

If an action URI is used then the action URI MUST consist of the wsat namespace URI concatenated with the "/" character and the element name. For example:

http://schemas.xmlsoap.org/ws/2004/10/wsat/Commit

1.3 XSD and WSDL Files

The following links hold the XML schema and the WSDL declarations defined in this document.

http://schemas.xmlsoap.org/ws/2004/10/wsat/wsat.xsd
http://schemas.xmlsoap.org/ws/2004/10/wsat/wsat.wsdl

Soap bindings for the WSDL documents defined in this specification MUST use "document" for the style attribute.
1.4 AT Protocol Elements

The protocol elements define various extensibility points that allow other child or attribute content. Additional children and/or attributes MAY be added at the indicated extension points but MUST NOT contradict the semantics of the parent and/or owner, respectively. If a receiver does not recognize an extension, the receiver SHOULD ignore the extension.
2 Introduction

The current set of Web service specifications [WSDL] [SOAP] defines protocols for Web service interoperability. Web services increasingly tie together a number of participants forming large distributed applications. The resulting activities may have complex structure and relationships.

The WS-Coordination specification defines an extensible framework for defining coordination types. This specification provides the definition of an atomic transaction coordination type used to coordinate activities having an "all or nothing" property. Atomic transactions commonly require a high level of trust between participants and are short in duration. The Atomic Transaction specification defines protocols that enable existing transaction processing systems to wrap their proprietary protocols and interoperate across different hardware and software vendors.

To understand the protocol described in this specification, the following assumptions are made:

- The reader is familiar with existing standards for two-phase commit protocols and with commercially available implementations of such protocols. Therefore this section includes only those details that are essential to understanding the protocols described.
- The reader is familiar with the WS-Coordination [WSCOOR] specification that defines the framework for the WS-AtomicTransaction coordination protocols.
- The reader is familiar with WS-Addressing [WSADDR] and WS-Policy [WSPOLICY].

Atomic transactions have an all-or-nothing property. The actions taken prior to commit are only tentative (i.e., not persistent and not visible to other activities). When an application finishes, it requests the coordinator to determine the outcome for the transaction. The coordinator determines if there were any processing failures by asking the participants to vote. If the participants all vote that they were able to execute successfully, the coordinator commits all actions taken. If a participant votes that it needs to abort or a participant does not respond at all, the coordinator aborts all actions taken. Commit makes the tentative actions visible to other transactions. Abort makes the tentative actions appear as if the actions never happened. Atomic transactions have proven to be extremely valuable for many applications. They provide consistent failure and recovery semantics, so the applications no longer need to deal with the mechanics of determining a mutually agreed outcome decision or to figure out how to recover from a large number of possible inconsistent states.

Atomic Transaction defines protocols that govern the outcome of atomic transactions. It is expected that existing transaction processing systems wrap their proprietary mechanisms and interoperate across different vendor implementations.
3 Atomic Transaction Context

Atomic Transaction builds on WS-Coordination, which defines an activation and a registration service. Example message flows and a complete description of creating and registering for coordinated activities is found in the WS-Coordination specification [WSCOOR].

The Atomic Transaction coordination context must flow on all application messages involved with the transaction.

Atomic Transaction adds the following semantics to the CreateCoordinationContext operation on the activation service.

If the request includes the CurrentContext element, the target coordinator is interposed as a subordinate to the coordinator stipulated inside the CurrentContext element.

If the request does not include a CurrentContext element, the target coordinator creates a new transaction and acts as the root.

A coordination context may have an Expires attribute. This attribute specifies the earliest point in time at which a transaction may be terminated solely due to its length of operation. From that point forward, the transaction manager may elect to unilaterally roll back the transaction, so long as it has not transmitted a Commit or a Prepared notification.

The Atomic Transaction protocol is identified by the following coordination type:

http://schemas.xmlsoap.org/ws/2004/10/wsat
4 Atomic Transaction Protocols

This specification defines the following protocols for atomic transactions.

- **Completion**: The completion protocol initiates commitment processing. Based on each protocol’s registered participants, the coordinator begins with Volatile 2PC then proceeds through Durable 2PC. The final result is signaled to the initiator.

- **Two-Phase Commit (2PC)**: The 2PC protocol coordinates registered participants to reach a commit or abort decision, and ensures that all participants are informed of the final result. The 2PC protocol has two variants:
  - **Volatile 2PC**: Participants managing volatile resources such as a cache should register for this protocol.
  - **Durable 2PC**: Participants managing durable resources such as a database should register for this protocol.

A participant can register for more than one of these protocols by sending multiple Register messages.

4.1 Preconditions

The correct operation of the protocols requires that a number of preconditions MUST be established prior to the processing:

1. The source MUST have knowledge of the destination’s policies, if any, and the source MUST be capable of formulating messages that adhere to this policy.
2. If a secure exchange of messages is required, then the source and destination MUST have a security context.

4.2 Completion Protocol

The Completion protocol is used by an application to tell the coordinator to either try to commit or abort an atomic transaction. After the transaction has completed, a status is returned to the application.

An initiator registers for this protocol using the following protocol identifier:

```
http://schemas.xmlsoap.org/ws/2004/10/wsat/Completion
```

The diagram below illustrates the protocol abstractly:
The coordinator accepts:

**Commit**
Upon receipt of this notification, the coordinator knows that the participant has completed application processing and that it should attempt to commit the transaction.

**Rollback**
Upon receipt of this notification, the coordinator knows that the participant has terminated application processing and that it should abort the transaction.

The initiator accepts:

**Committed**
Upon receipt of this notification, the initiator knows that the coordinator reached a decision to commit.

**Aborted**
Upon receipt of this notification, the initiator knows that the coordinator reached a decision to abort.

Conforming implementations must implement Completion.

### 4.3 Two-Phase Commit Protocol

The Two-Phase Commit (2PC) protocol is a Coordination protocol that defines how multiple participants reach agreement on the outcome of an atomic transaction. The 2PC protocol has two variants: Durable 2PC and Volatile 2PC.

#### 4.3.1 Volatile Two-Phase Commit Protocol

Upon receiving a Commit notification in the completion protocol, the root coordinator begins the prepare phase of all participants registered for the Volatile 2PC protocol. All participants registered for this protocol must respond before a Prepare is issued to a participant registered for Durable 2PC. Further participants may register with the coordinator until the coordinator issues a Prepare to any durable participant. A volatile recipient is not guaranteed to receive a notification of the transaction's outcome.

Participants register for this protocol using the following protocol identifier:

```
http://schemas.xmlsoap.org/ws/2004/10/wsat/Volatile2PC
```
4.3.2 Durable Two-Phase Commit Protocol

After receiving a Commit notification in the completion protocol and upon successfully completing the prepare phase for Volatile 2PC participants, the root coordinator begins the Prepare phase for Durable 2PC participants. All participants registered for this protocol must respond Prepared or ReadOnly before a Commit notification is issued to a participant registered for either protocol.

Participants register for this protocol using the following protocol identifier:

http://schemas.xmlsoap.org/ws/2004/10/wsat/Durable2PC

4.3.3 2PC Diagram and Notifications

The diagram below illustrates the protocol abstractly:

The participant accepts:

Prepare

Upon receipt of this notification, the participant knows to enter phase 1 and vote on the outcome of the transaction. If the participant does not know of the transaction, it must vote to abort. If the participant has already voted, it should resend the same vote.

Rollback

Upon receipt of this notification, the participant knows to abort, and forget, the transaction. This notification can be sent in either phase 1 or phase 2. Once sent, the coordinator may forget all knowledge of this transaction.

Commit

Upon receipt of this notification, the participant knows to commit the transaction. This notification can only be sent after phase 1 and if the participant voted to commit. If the participant does not know of the transaction, it must send a Committed notification to the coordinator.

The coordinator accepts:

Prepared

Upon receipt of this notification, the coordinator knows the participant is prepared and votes to commit the transaction.
Upon receipt of this notification, the coordinator knows the participant votes to commit the transaction, and has forgotten the transaction. The participant does not wish to participate in phase 2.

Upon receipt of this notification, the coordinator knows the participant has aborted, and forgotten, the transaction.

Upon receipt of this notification, the coordinator knows the participant has committed the transaction. That participant may be safely forgotten.

Upon receipt of this notification, the coordinator may assume the participant has suffered a recoverable failure. It should resend the last appropriate protocol notification.

Conforming implementations MUST implement the 2PC protocol.
5 AT Policy Assertion

WS-Policy Framework [WS-Policy] and WS-Policy Attachment [WS-PolicyAttachment] collectively define a framework, model and grammar for expressing the capabilities, requirements, and general characteristics of entities in an XML Web services-based system. To enable a web service to describe transactional capabilities and requirements of a service and its operations, this specification defines a pair of Atomic Transaction policy assertions that leverage the WS-Policy framework.

5.1 Assertion Model

The AT policy assertions are provided by a web service to qualify the transactional processing of messages associated with the particular operation to which the assertions are scoped. The AT policy assertions indicate:

1. whether a requester MAY, MUST or SHOULD NOT include an AtomicTransaction CoordinationContext flowed with the message.
2. the capability of the target service to process the message under an atomic transaction regardless of whether the requester supplies an AtomicTransaction CoordinationContext.

The AT policy assertions are semantically independent of one another, and may be used together or in isolation.

5.2 Normative Outline

The normative outlines for the AT policy assertions are:

```xml
<wsat:ATAssertion [wsp:Optional="true"]? ... />
... 
</wsat:ATAssertion>
```

The following describes additional, normative constraints on the outline listed above:

```xml
<wsat:ATAlwaysCapability ... /> 
```

Per WS-Policy [WS-Policy], this is compact notation for two policy alternatives, one with and one without the assertion. Presence of both policy alternatives indicates that the behavior indicated by the assertion is optional, such that an atomic transaction MAY be flowed inside a requester’s message. The absence of the assertion is interpreted to mean that a transaction SHOULD NOT be flowed inside a requester’s message.

```xml
<wsat:ATAlwaysCapability ... />
```

The following describes additional, normative constraints on the outline listed above:
A policy assertion that specifies a capability of the target service indicating that a requester’s message will be processed transactionally regardless of whether the requester supplies an AtomicTransaction CoordinationContext. If an AtomicTransaction context is provided by the requester, it will be used. Otherwise the processing of the message will be within a transaction implicitly started and ended by the target service’s environment as part of the processing of that message.

5.3 Assertion Attachment

Because the AT policy assertions indicate atomic transaction behavior for a single operation, the assertions have Operation Policy Subject [WS-PolicyAttachment].

WS-PolicyAttachment defines two WSDL [WSDL 1.1] policy attachment points with Operation Policy Subject:

- `wsdl:portType/wsdl:operation` – A policy expression containing the AT policy assertion MUST NOT be attached to a `wsdl:portType`; the AT policy assertions specify a concrete behavior whereas the `wsdl:portType` is an abstract construct.

- `wsdl:binding/wsdl:operation` – A policy expression containing the AT policy assertions SHOULD be attached to a `wsdl:binding`.

5.4 Assertion Example

An example use of the AT policy assertion follows:

```
<wsdl:definitions

targetNamespace="bank.example.com"

xmlns:tns="bank.example.com"

xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"

xmlns:wsat="http://schemas.xmlsoap.org/ws/2004/10/wsat"

xmlns:wsu="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-utility-1.0.xsd" >

<wsp:Policy wsu:Id="TransactedPolicy1" >

<wsat:ATAssertion wsp:optional="true" />

<!-- omitted assertions -->

</wsp:Policy>

<wsp:Policy wsu:Id="TransactedPolicy2" >

<wsat:ATAlwaysCapability />

<!-- omitted assertions -->

</wsp:Policy>

<wsd:binding name="BankBinding" type="tns:BankPortType" >

<!-- omitted elements -->

</wsp:Policy>
```
(20)     <wsdl:operation name="QueryBalance" >
(21)       <wsp:PolicyReference URI="#TransactedPolicy2" 
wsdl:required="true" />
(22)       <!-- omitted elements -->
(23)     </wsdl:operation>
(24)     <wsdl:operation name="TransferFunds" >
(25)       <wsp:PolicyReference URI="#TransactedPolicy1" 
wsdl:required="true" />
(26)       <!-- omitted elements -->
(27)     </wsdl:operation>
(28)   </wsdl:binding>
(29) </wsdl:definitions>

Lines (9-12) are a policy expression that includes an AT policy assertion (Line 10) to indicate that an atomic transaction in WS-Coordination [WS-Coordination] format MAY be used.

Lines (13-16) are a policy expression that includes an AT policy assertion (Line 14) to indicate that a capability of the target service is that it will process messages in a transaction regardless of whether any AtomicTransaction CoordinationContext is sent by the requester.

Lines (20-23) are a WSDL [WSDL 1.1] binding. Line (21) indicates that the policy in Lines (13-16) applies to this binding, specifically indicating that QueryBalance messages are processed in an atomic transaction regardless of whether a requester provides an AtomicTransaction CoordinationContext.

Lines (24-27) are a WSDL [WSDL 1.1] binding. Line (25) indicates that the policy in Lines (9-12) applies to this binding, specifically indicating that an atomic transaction MAY flow inside messages.
6 Transaction Faults

WS-AtomicTransaction faults MUST include as the [action] property the following fault action URI:

\[
\text{http://schemas.xmlsoap.org/ws/2004/10/wsat/fault}
\]

The faults defined in this section are generated if the condition stated in the preamble is met. Faults are targeted at a destination endpoint according to the fault handling rules defined in [WSADDR].

The definitions of faults in this section use the following properties:

- **[Code]** The fault code.
- **[Subcode]** The fault subcode.
- **[Reason]** The English language reason element.
- **[Detail]** The detail element. If absent, no detail element is defined for the fault.

For SOAP 1.2, the [Code] property MUST be either "Sender" or "Receiver". These properties are serialized into text XML as follows:

<table>
<thead>
<tr>
<th>SOAP Version</th>
<th>Sender</th>
<th>Receiver</th>
</tr>
</thead>
<tbody>
<tr>
<td>SOAP 1.2</td>
<td>S:Sender</td>
<td>S:Receiver</td>
</tr>
</tbody>
</table>

The properties above bind to a SOAP 1.2 fault as follows:

```
<S:Envelope>
  <S:Header>
    <wsa:Action>
      http://schemas.xmlsoap.org/ws/2004/10/wsat/fault
    </wsa:Action>
  </S:Header>
  <S:Body>
    <S:Fault>
      <S:Code>
        <S:Value>[Code]</S:Value>
      </S:Code>
      <S:Subcode>
        <S:Value>[Subcode]</S:Value>
      </S:Subcode>
      <S:Reason>
        <S:Text xml:lang="en">[Reason]</S:Text>
      </S:Reason>
      <S:Detail>
        [Detail]
      </S:Detail>
    </S:Fault>
  </S:Body>
</S:Envelope>
```

The properties bind to a SOAP 1.1 fault as follows:

```
<S11:Envelope>
  <S11:Body>
    <S11:Fault>
    </S11:Code>
    </S11:Reason>
    <S11:Detail>[Detail]
    ...</S11:Detail>
  </S11:Fault>
</S11:Body>
</S11:Envelope>
```
6.1 InconsistentInternalState

This fault is sent by a participant to indicate that it cannot fulfill its obligations. This indicates a global consistency failure and is an unrecoverable condition.

Properties:

[Code] Sender

[Subcode] wsat:InconsistentInternalState

[Reason] A global consistency failure has occurred. This is an unrecoverable condition.

[Detail] unspecified
7 Security Model

The security model for atomic transactions builds on the model defined in WS-Coordination [WSCOOR]. That is, services have policies specifying their requirements and requestors provide claims (either implicit or explicit) and the requisite proof of those claims. Coordination context creation establishes a base secret which can be delegated by the creator as appropriate.

Because atomic transactions represent a specific use case rather than the general nature of coordination contexts, additional aspects of the security model can be specified.

All access to atomic transaction protocol instances is on the basis of identity. The nature of transactions, specifically the uncertainty of systems means that the security context established to register for the protocol instance may not be available for the entire duration of the protocol.

Consider for example the scenarios where a participant has committed its part of the transaction, but for some reason the coordinator never receives acknowledgement of the commit. The result is that when communication is re-established in the future, the coordinator will attempt to confirm the commit status of the participant, but the participant, having committed the transaction and forgotten all information associated with it, no longer has access to the special keys associated with the token.

The participant can only prove its identity to the coordinator when it indicates that the specified transaction is not in its log and assumed committed. This is illustrated in the figure below:

![Diagram](image_url)

There are, of course, techniques to mitigate this situation but such options will not always be successful. Consequently, when dealing with atomic transactions, it is critical that identity claims always be proven to ensure that correct access control is maintained by coordinators.

There is still value in coordination context-specific tokens because they offer a bootstrap mechanism so that all participants need not be pre-authorized. As well, it provides additional security because only those instances of an identity with access to the token will be able to securely interact with the coordinator (limiting privileges strategy). This is illustrated in the figure below:
The "list" of authorized participants ensures that application messages having a coordination context are properly authorized since altering the coordination context ID will not provide additional access unless (1) the bootstrap key is provided, or (2) the requestor is on the authorized participant "list" of identities.
8 Security Considerations

It is strongly RECOMMENDED that the communication between services be secured using the mechanisms described in WS-Security [WSSec]. In order to properly secure messages, the body and all relevant headers need to be included in the signature. Specifically, the `<wscoor:CoordinationContext>` header needs to be signed with the body and other key message headers in order to "bind" the two together.

In the event that a participant communicates frequently with a coordinator, it is RECOMMENDED that a security context be established using the mechanisms described in WS-Trust [WSTrust] and WS-SecureConversation [WSSecConv] allowing for potentially more efficient means of authentication.

It is common for communication with coordinators to exchange multiple messages. As a result, the usage profile is such that it is susceptible to key attacks. For this reason it is strongly RECOMMENDED that the keys be changed frequently. This "re-keying" can be effected a number of ways. The following list outlines four common techniques:

- Attaching a nonce to each message and using it in a derived key function with the shared secret
- Using a derived key sequence and switch "generations"
- Closing and re-establishing a security context (not possible for delegated keys)
- Exchanging new secrets between the parties (not possible for delegated keys)

It should be noted that the mechanisms listed above are independent of the SCT and secret returned when the coordination context is created. That is, the keys used to secure the channel may be independent of the key used to prove the right to register with the activity.

The security context MAY be re-established using the mechanisms described in WS-Trust [WSTrust] and WS-SecureConversation [WSSecConv]. Similarly, secrets can be exchanged using the mechanisms described in WS-Trust. Note, however, that the current shared secret SHOULD NOT be used to encrypt the new shared secret. Derived keys, the preferred solution from this list, can be specified using the mechanisms described in WS-SecureConversation.

The following list summarizes common classes of attacks that apply to this protocol and identifies the mechanism to prevent/mitigate the attacks:

- **Message alteration** – Alteration is prevented by including signatures of the message information using WS-Security [WSSec].
- **Message disclosure** – Confidentiality is preserved by encrypting sensitive data using WS-Security.
- **Key integrity** – Key integrity is maintained by using the strongest algorithms possible (by comparing secured policies – see WS-Policy [WSPOLICY] and WS-SecurityPolicy [WSSecPolicy]).
- **Authentication** – Authentication is established using the mechanisms described in WS-Security and WS-Trust [WSTrust]. Each message is authenticated using the mechanisms described in WS-Security [WSSec].
- **Accountability** – Accountability is a function of the type of and string of the key and algorithms being used. In many cases, a strong symmetric key provides sufficient accountability. However, in some environments, strong PKI signatures are required.
**Availability** – Many services are subject to a variety of availability attacks. Replay is a common attack and it is RECOMMENDED that this be addressed as described in the next bullet. Other attacks, such as network-level denial of service attacks are harder to avoid and are outside the scope of this specification. That said, care should be taken to ensure that minimal processing be performed prior to any authenticating sequences.

**Replay** – Messages may be replayed for a variety of reasons. To detect and eliminate this attack, mechanisms should be used to identify replayed messages such as the timestamp/nonce outlined in WS-Security [WSSec]. Alternatively, and optionally, other technologies, such as sequencing, can also be used to prevent replay of application messages.
9 Use of WS-Addressing Headers

The messages defined in WS-Coordination and WS-AtomicTransaction can be classified into four types:

Request messages: CreateCoordinationContext and Register.
Reply messages: CreateCoordinationContextResponse and RegisterResponse.
Notication messages: Commit, Rollback, Committed, Aborted, Prepare, Prepared, ReadOnly and Replay.
Fault messages

Request and reply messages follow the standard "Request Reply" pattern as defined in WS-Addressing.
Notification messages follow the standard "one way" pattern as defined in WS-Addressing. There are two types of notification messages:

A notification message is a terminal message when it indicates the end of a coordinator/participant relationship. Committed, Aborted and ReadOnly are terminal messages.
A notification message is not a terminal message when it does not indicate the end of a coordinator/participant relationship. Commit, Rollback, Prepare, Prepared and Replay are not terminal messages.

The following statements define addressing interoperability requirements for the respective WS-Coordination and WS-AtomicTransaction message types:

Request messages
MUST include a wsa:MessageID header.
MUST include a wsa:ReplyTo header.

Reply messages
MUST include a wsa:RelatesTo header, specifying the MessageID from the corresponding Request message.

Non-terminal notification messages
MUST include a wsa:ReplyTo header

Terminal notification messages
SHOULD NOT include a wsa:ReplyTo header

Fault messages
MUST include a wsa:RelatesTo header, specifying the MessageID from the Request or Notification message that generated the fault condition.

Notification messages are addressed by both coordinators and participants using the Endpoint References initially obtained during the Register-RegisterResponse exchange. If a wsa:ReplyTo header is present in a notification message it MAY be used by the recipient, for example in cases where a Coordinator or Participant has forgotten a transaction that is completed and needs to respond to a resent...
protocol message. Permanent loss of connectivity between a coordinator and a participant in an in-doubt state can result in data corruption.

If a wsa:FaultTo header is present on a message that generates a fault condition, then it MUST be used by the recipient as the destination for any fault. Otherwise, fault messages MAY be addressed by both coordinators and participants using the Endpoint References initially obtained during the Register:RegisterResponse exchange.

All messages are delivered using connections initiated by the sender. Endpoint References MUST contain physical addresses and MUST NOT use well-known "anonymous" endpoint defined in WS-Addressing.

The following state tables specify the behavior of coordinators and participants when presented with protocol messages or internal events. These tables present the view of a coordinator or participant with respect to a single partner. A coordinator with multiple participants can be understood as a collection of independent coordinator state machines.

Each cell in the tables uses the following convention:

<table>
<thead>
<tr>
<th>Legend</th>
</tr>
</thead>
<tbody>
<tr>
<td>action to take next state</td>
</tr>
</tbody>
</table>

Each state supports a number of possible events. Expected events are processed by taking the prescribed action and transitioning to the next state. Unexpected protocol messages will result in a fault message, with a standard fault code such as Invalid State or Inconsistent Internal State. Events that may not occur in a given state are labelled as N/A.
## Atomic Transaction 2PC protocol (Coordinator View)

<table>
<thead>
<tr>
<th>Inbound Events</th>
<th>States</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>None</td>
</tr>
<tr>
<td>Register</td>
<td>Invalid State None</td>
</tr>
<tr>
<td>Prepared</td>
<td>Durable: Send Rollback, Inval State Not</td>
</tr>
<tr>
<td>Read Only</td>
<td>Ignore None</td>
</tr>
<tr>
<td>Aborted</td>
<td>Ignore None</td>
</tr>
<tr>
<td>Committed</td>
<td>Ignore None</td>
</tr>
<tr>
<td>Replay</td>
<td>Durable: Send Rollback, Inval State Not</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Internal Events</th>
<th>States</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Return Aborted None</td>
</tr>
<tr>
<td>User Commit</td>
<td>Return Aborted None</td>
</tr>
<tr>
<td>User Rollback</td>
<td>N/A</td>
</tr>
<tr>
<td>Expires Times out</td>
<td>N/A</td>
</tr>
<tr>
<td>Comms Times out</td>
<td>N/A</td>
</tr>
<tr>
<td>Commit Decision</td>
<td>N/A</td>
</tr>
<tr>
<td>Write Done</td>
<td>N/A</td>
</tr>
<tr>
<td>Write Failed</td>
<td>N/A</td>
</tr>
<tr>
<td>All Forgotten</td>
<td>N/A</td>
</tr>
</tbody>
</table>

### Notes:

1. Transitions with a "N/A" as their action are inexpressible. A TM should view these transitions as serious internal consistency issues, and probably fatal.
2. Internal events are those that are created either within a TM itself, or on its local system.
“Forget” implies that the subordinate’s participation is removed from the coordinator (if necessary), and otherwise the message is ignored.

### Atomic Transaction 2PC protocol (Participant View)

<table>
<thead>
<tr>
<th>Inbound Events</th>
<th>States</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>No</td>
</tr>
<tr>
<td>Register Response</td>
<td>Register Subordinate Active</td>
</tr>
<tr>
<td>Prepare</td>
<td>Send Aborted, Ignored</td>
</tr>
<tr>
<td>Commit</td>
<td>Send Committed, Ignored</td>
</tr>
<tr>
<td>Rollback</td>
<td>Send Aborted, Ignored</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Internal Events</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

### Notes:

1. Transitions with a “N/A” as their action are inexpressible. A TM should view these transitions as serious internal consistency issues, and probably fatal.

2. Internal events are those that are created either within a TM itself, or on its local system.
