

# Application Notes for WS-Reliability 1.1 Version 1.0

## Committee Draft 01

30 March 2007

**Specification URIs:**

**This Version:**

<http://docs.oasis-open.org/wsrn/application-notes-cd-01.pdf>

**Latest Approved Version:**

<http://docs.oasis-open.org/wsrn/application-notes-cd-01.pdf>

**Technical Committee:**

OASIS WS Reliable Messaging TC

**Chair(s):**

Tom Rutt

**Editor(s):**

Jacques Durand

**Related work:**

This specification is related to:

- WS-Reliability 1.1

**Declared XML Namespace(s):**

None

**Abstract:**

This document describes how applications might use the WS-Reliability specification.

**Status:**

This document has been approved as a **committee draft** of the OASIS Web Services Reliable Messaging (WSRM) Technical Committee.

Committee members should send comments on this document to the [wsrn@lists.oasis-open.org](mailto:wsrn@lists.oasis-open.org) list. Others should subscribe to and send comments to the [wsrn-comment@lists.oasis-open.org](mailto:wsrn-comment@lists.oasis-open.org) list. To subscribe, send an email message to [wsrn-comment-request@lists.oasis-open.org](mailto:wsrn-comment-request@lists.oasis-open.org) with the word "subscribe" as the body of the message.

For information on whether any patents have been disclosed that may be essential to implementing this specification, and any offers of patent licensing terms, please refer to the Intellectual Property Rights section of the WSRM TC web page (<http://www.oasis-open.org/committees/wsrn/>).

# 1 Introduction

2 This document presents non-normative information that may be of benefit to WS-Reliability [WS-  
3 Reliability] application developers. It provides a guide for WS-Reliability application developers who  
4 already understand the fundamentals of developing a WS-Reliability application.

5 The purpose of this document is to answer common questions that might arise during WS- Reliability  
6 application development by means of non-normative scenarios and examples. Additionally, this document  
7 may also serve as an aid to clarify potential usage scenarios of WS-Reliability. The intended audience of  
8 this document are WS-Reliability application designers

9 Each section of this document is addressing a different aspect of WS-Reliability application development.  
10 Each section contains information on best practices, along with examples, or reference to examples  
11 elsewhere.

12 This document does not present a full end-to-end WS-Reliability example and is not meant as an entry  
13 point to WS-Reliability.

14 For normative descriptions of WS-Reliability, readers should refer to the WS-Reliability specification [WS-  
15 Reliability].

## 2 Application Notes relating to Reliable Sending of Response Messages

### 2.1 Problem Statement

Business payloads are often carried over protocol responses. This is the case in request-response message exchange patterns or when message pulling is being used (e.g. by e-Business SME partners in order to overcome their connectivity constraints). The WS-Reliability 1.1 specification does not distinguish between reliability of a request and reliability of a response. It assumes that a message that is not acknowledged - whether request or response - may always be resent by an implementation. In practice, the resending of such response messages is posing challenges that require a proper resolution – and preferably the same resolution across implementations in order to interoperate.

This guideline document makes a recommendation on how to ensure At-Least-Once reliability (GuaranteedDelivery agreement) to the response leg of a two-way protocol (see definition in next section) that is underlying to SOAP. It also describes what features that are stated as optional in the specification, must be supported by the implementation.

### 2.2 Terminology

Two-way protocol: An underlying transport protocol is qualified here as "two-way" if: (a) it guarantees a channel for transferring the response of every message (request) initiated by an MSH, back to this MSH without need for explicit addressing information in SOAP headers and regardless of connectivity restrictions such as inability to accept incoming new connections, and (b) it provides some means to the MSH initiator of the exchange for correlating the response with the request, without relying on the SOAP header. For example, HTTP qualifies as two-way, but SMTP and FTP do not (although FTP has a notion of session, it does not inherently support the coupling of (b)).

Back-channel: The channel offered by the request message in a two-way protocol is also called back-channel in this specification.

Response message: a response message is implicitly understood as a message sent over the back-channel offered by another message (the request message).

NOTE: the reliability model in WS-Reliability is described for messages submitted to an implementation via "Submit" operation, and delivered via "Deliver" operation. A response message is supposed to be submitted via the "Respond" operation. It is assumed in this document that the reliability semantics extends to messages submitted via "Respond".

### 2.3 Implementation Guidelines

In 3.2.2 (Duplicate Elimination section) of [WS-Reliability], the following requirement is stated:

*When the Response RM-Reply Pattern is requested with Duplicate Elimination for a Reliable Message, the Receiving RMP cannot deliver that message to the Consumer again (because it is a duplicate of a previously delivered message), and a Consumer response payload is expected,*

58 *the response of the SOAP MEP instance MUST contain one (but not both) of the following:*  
59 *(a)- a copy of the original response payload returned for that Message (in the SOAP Body)*  
60 *in addition to the Acknowledgment Indication (in the SOAP Header) or*  
61 *(b)- a SOAP server Fault.*

62 The option (a) requires the implementation to have the ability to cache a response message that had  
63 already been sent, and to be able to resend it later in case a duplicate of the request is received.

64 The solution recommended here for ensuring the reliability of a response message, requires that  
65 an implementation supports option (a). The initial response produced for the first request message  
66 received and delivered, must be cached until expiration or until it is acknowledged, whichever comes first.  
67

## 68 **2.4 Usage Recommendation**

69

70 How to set the reliability for the request message:

71

72 Intuitively, the reliability of a response message in a request-response MEP depends on the reliability of  
73 the request message.

74 As a prerequisite to supporting GuaranteedDelivery for a response message, a user must ensure that the  
75 following reliability agreements are in use for the request message:

- 76 • GuaranteedDelivery. The reply pattern must be "Response".
- 77 • DuplicateElimination. In addition, the implementation must exhibit the behaviour (a) stated in the  
78 previous section (3.3), when a request message duplicate is received.

79 Considerations about notification of delivery failure:

80 When sending a request message, the RMP is not necessarily aware of the MEP that this request  
81 belongs to. It usually has no way to know whether a response message was expected or if this response  
82 was sent reliably. The Producer application of the request is assumed to have access to this knowledge.

83 Consequently, when a request message does not get acknowledged, a delivery failure notified to its  
84 Producer could mean either (1) the request failed to be delivered to the other party, or (2) the request was  
85 delivered, but the response – along with the request acknowledgement – failed to be delivered, in case a  
86 response was expected. In both cases, before concluding that a delivery failure has occurred, the request  
87 will be resent, providing an opportunity to resend the cached response, had it failed before.

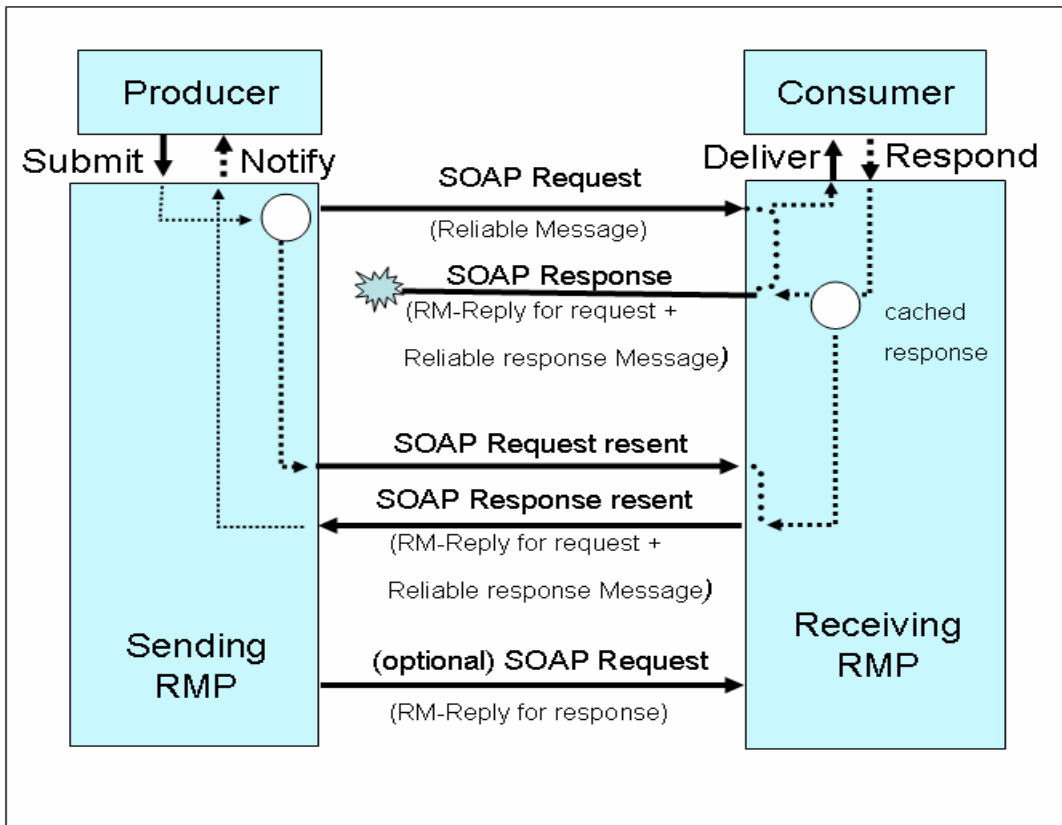

88 Given the above, request acknowledgement (or failure to get one) is sufficient to ensure the following: (1)  
89 resending of the response message as a consequence of resending the request message, (2) delivery  
90 failure notification for both request and response, to the request Producer party. However, without  
91 acknowledgment of the response, the response producer must be willing to cache each response until its  
92 request message expires since it would not receive delivery failure notifications for its responses. In  
93 some cases, a producer may choose to request an acknowledgment of receipt of its response  
94 messages.. This response acknowledgment will serve the following objectives:

95 (a) More efficient cache management, since the response may be removed from the cache when its  
96 acknowledgment is received.

97 (b) Notification the request Consumer party of failure to deliver its response message (even though the  
98 request Producer was also notified).

99 In case an implementation adds the wsm:Request element with an AckRequested element to the  
100 response message, the RM-Reply Pattern value must be "Callback".

101 The following figure illustrates a reliable exchange request-response, with both messages being  
102 acknowledged. Both request message and response message are cached for resending purpose.  
103 Duplicate elimination for the request prevents the request message from being delivered twice in case the  
104 request is resent.
