

An OASIS WS-Calendar White Paper

Conceptual Overview of WS-Calendar CD01

Understanding inheritance using the semantic elements of web services

By Toby Considine
On behalf of the OASIS WS-Calendar Technical Committee

WS-Calendar defines calls and semantics to perform temporal alignment in web services interactions. Short running services traditionally have been handled as if they were instantaneous, and have used just-in-time requests for scheduling. Longer running processes, including physical processes, may require significant lead times. When multiple long-running services participate in the same business process, it may be more important to negotiate a common completion time than a common start time. WS-Calendar extends the well-known semantics and interactions built around iCalendar and applies them to service coordination. This white paper explains some of the issues in generic service coordination as an aid to understanding how and when to use WS-Calendar

This white paper was produced and approved by the OASIS WS-Calendar Technical Committee as a Committee Draft. It has not been reviewed and/or approved by the OASIS membership at-large.

68 Why WS-Calendar, why now?

69 As physical resources become scarcer, it is imperative to manage the systems that
70 manage our physical world just as we manage business and personal services. The
71 controlling paradigm of our resources shifts from static efficiency to just-in-time provision
72 of services. At the same time, technology and policy are moving toward reliance on
73 resources that are intermittently available, creating another constantly changing schedule.
74 The challenge of the internet of things is to manage the collision of these schedules.

75 Service oriented architecture has seen growing use in IT as a paradigm for organizing and
76 utilizing distributed capabilities that may be under the control of different ownership
77 domains. It is natural to think of one computer agent's requirements being met by a
78 computer agent belonging to a different owner. The granularity of needs and capabilities
79 vary from fundamental to complex, and any given need may require the combining of
80 numerous capabilities while any single capability may address more than one need. SOA
81 is seen to provide a powerful framework for matching needs and capabilities and for
82 combining capabilities to address those needs. The purpose of using a capability is to
83 realize one or more real world effects. When we expose these capabilities for remote
84 interaction, we refer to it as a service.

85 Physical processes are already being coordinated by web services. Building systems and
86 industrial processes are operated using oBIX, BACnet/WS, LON-WS, OPC XML, and a
87 number of proprietary specifications including TAC-WS, Gridlogix EnNet, and
88 MODBUS.NET. In particular, if building systems coordinate with the schedules of the
89 building's occupants, they can reduce energy use while improving performance.

90 Service interactions have typically lacked a notion of schedule or of temporal coordination.
91 Short running services have been handled as if they were instantaneous, and schedules
92 have been managed through just-in-time requests. Longer running processes, including
93 physical processes, may require significant lead times. Long-running processes have
94 different dynamics than do short ones. For example, it may it may be more important in
95 some scenarios to negotiate a common completion time than a common start time.

96 Physical services rely on a diverse mix of technologies that may be in place for decades.
97 Direct control of diverse technologies requires in-depth knowledge of each technology.
98 Approaches that rely on direct control of services by a central system increase integration
99 costs and reduce interoperability. Interaction patterns that increase schedule autonomy
100 free up such systems for technical innovations by reducing the need for a central agent to
101 know and manage multiple lead times.

102 An increasing number of efforts are underway that require synchronization of processes
103 on an "internet scale". Efforts to build an intelligent power grid (or smart grid) rely on
104 coordinating processes in homes, offices, and industry with projected and actual power
105 availability; these efforts envision communicating different price schedules at different
106 times. Emergency management coordinators wish to inform geographic regions of future
107 events, such as a projected tornado touchdown. The open Building Information Exchange
108 specification (OBIX) lacks a common schedule communications for interaction with
109 enterprise activities. These and other efforts benefit from a common cross-domain, cross
110 specification standard for communicating schedule and interval.

111 **WS-Calendar builds on iCalendar**

112 For human interactions and human scheduling, the well-known iCalendar format
113 addresses these problems. Prior to WS-Calendar, there has been no comparable
114 standard for web services. As an increasing number of physical processes become
115 managed by web services, the lack of a similar standard for scheduling and coordination
116 of services becomes critical.

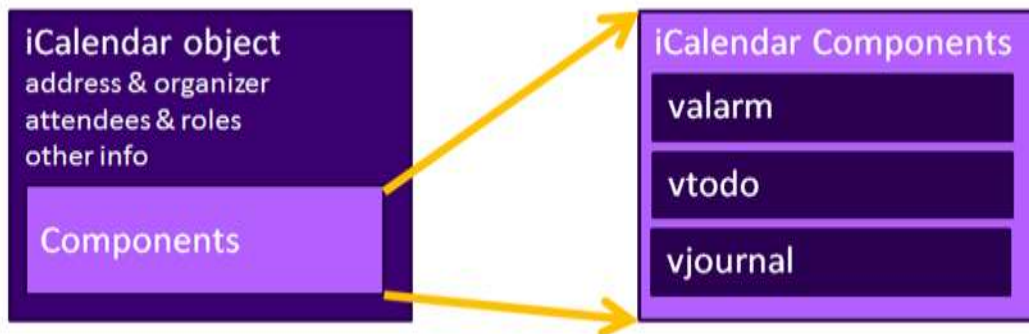

117 WS-Calendar is part of a concerted effort to address the issues above. CalConnect,
118 working through the IETF, has updated the RFC for iCalendar to support extensibility
119 [RFC 5545]. They have submitted a standard for XML serialization of iCalendar which the
120 WS-Calendar specification relies on heavily.

121 The intent of the WS-Calendar technical committee was to adapt the existing
122 specifications for calendaring and apply them to develop a standard for how schedule and
123 event information is passed between and within services. The standard adopts the
124 semantics and vocabulary of iCalendar for application to the completion of web service
125 contracts. WS Calendar builds on work done and ongoing in The Calendaring and
126 Scheduling Consortium (CalConnect), which works to increase interoperability between
127 calendaring systems.

128 **Building on iCalendar's Components**

129 The iCalendar object includes many elements to support distributed scheduling and
130 authorization for events. Transactions are committed based upon distributed decisions
131 communicated by systems that are frequently off-line. Calendar management is a rich and
132 complex problem whose solutions and techniques are robust and mature. WS-Calendar
133 includes service definitions to invoke these behaviors.

134 At the heart of the iCalendar message is the components collection. WS-Calendar
135 extends the semantics of these components to meet the needs of service integration.

136

137

138

Figure 1: iCalendar specifies scheduling components that are well known and well understood

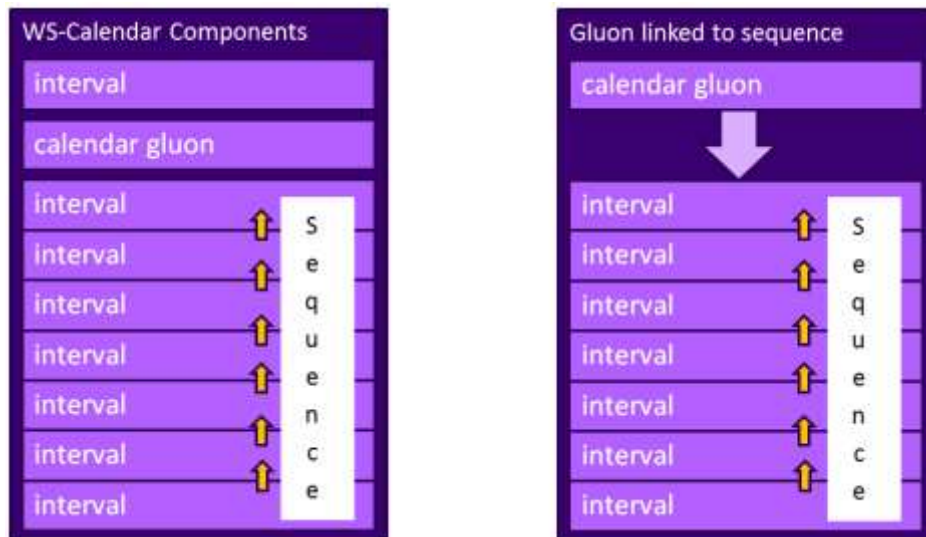

139 Don't worry. You won't see the iCalendar components (vobjects) again. WS-Calendar
140 inherits behaviors and attributes from the iCalendar components to define the Interval, the
141 Sequence and the Calendar Gluon. WS-Calendar builds services scheduling and
142 performance alignment upon these three components. Because of the inheritance, these
143 objects can travel within and interact with the world of today's calendars.

144 Semantic Components of WS-Calendar

145 WS-Calendar semantics define a structure for the common expression of schedules for
146 events or a series of events. Because physical processes may require other supporting
147 services, scheduling of the services described in these structures may be constrained in
148 performance; you can't schedule a reception at a hotel without also scheduling a set-up
149 and a clean-up. WS-Calendar enables the expression of such relationships without
150 requiring the calling party to understand the supporting processes.

151 Other processes may involve parameterized negotiations between services. Intervals may
152 be of fixed or variable duration. Purchase prices and quantities may vary over time. The
153 intervals may be consecutive, or intermittent. WS-Calendar provides a common
154 mechanism for elaborating these details using inheritance and local over-rides to enable
155 remote invocation, controlled patterns for service specification, and two-way negotiation
156 while achieving parsimonious serialization.

157 The Core Components

158

159

Figure 2: Intervals and Calendar Gluons

160 The core components of WS-Calendar are the Interval and the Calendar Gluon. Each of
161 these inherits definitions and structure from the iCalendar components.

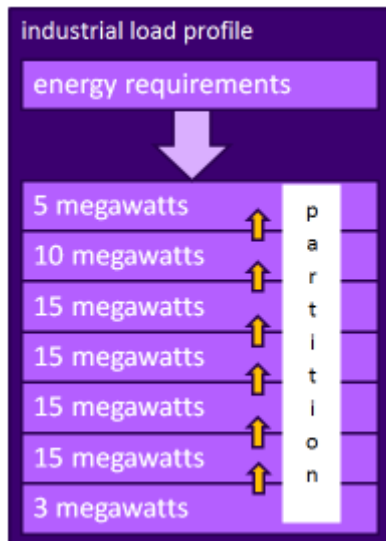

162 Intervals

163 The Interval is a length of time associated with service performance. Each interval has a
164 defined payload of XML information. When an interval has a scheduled start time or end
165 time, then we call it a Scheduled Interval.

166 iCalendar components include Relations, whereby the message publisher can specify
167 relationships between components. The iCalendar relationships are PARENT, CHILD,
168 SIBLING, START, and END. WS-Calendar extends this list with Temporal Relationships:
169 STARTFINISH, STARTSTART, FINISHSTRT, FINISHFINISH, each with an offset
170 expressed as a duration. Intervals and relationships together define Sequences.

171 **Sequences**

172 A Sequence is a collection of intervals with defined temporal relationships. The simplest
173 sequence is set of consecutive intervals of the same duration. WS-Calendar names such
174 a simple, regular Sequence a Partition.

175

176

Figure 3: The Partition, the simplest Sequence

177 Figure 3 depicts a simple repeating time interval along with a single external expression of
178 the type of information provided by each interval. In Figure 3, it is labeled Energy
179 Requirements; in WS-Calendar, this is an instance of a Calendar Gluon (see below).

180 The intervals in a sequence have a coherent set of relationships between them. The
181 collection of Intervals in Figure 3 defines a period of time, but not a particular period; there
182 is no start or end time for any of the Intervals. If a single interval of a Sequence is
183 scheduled, one can compute the schedule for each of them. A particular service
184 interaction can schedule the Sequence by defining a Start Date and Time. Another
185 interaction could schedule the same Sequence again with a different Start Date and Time.

186 **Calendar Gluons**

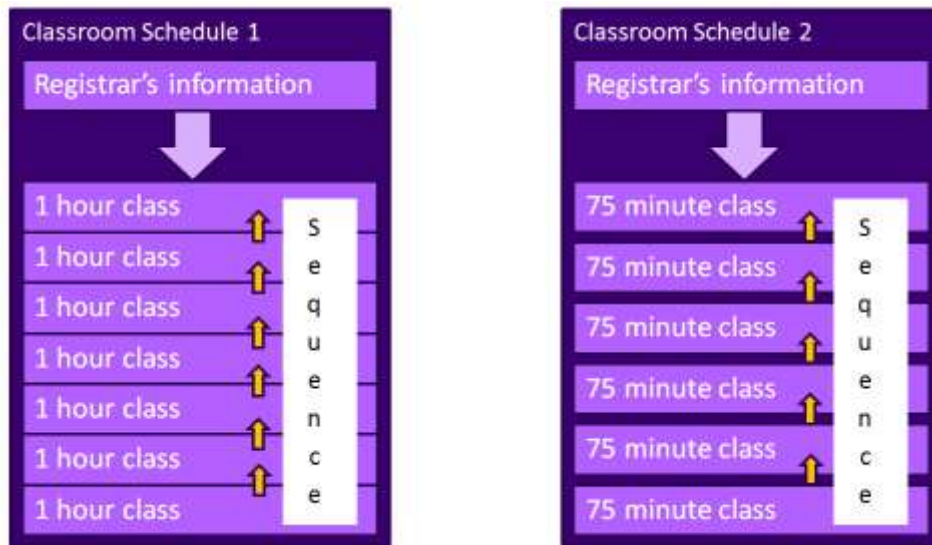

187 Calendar Gluons hold information to define an interval. Any information specified in an
188 Interval can also be specified in the Calendar Gluon. So why have a Calendar Gluon?

189 In physics, Gluons act to mediate as well as to participate in the interactions between
190 quarks. A Calendar Gluon defines information to be inherited by each Interval in the
191 Sequence, as well as scheduling the entire sequence.

192 Referring again to the Industrial Load Profile in Figure 3, the Calendar Gluon specifies that
193 each Interval is defining Energy Requirements. The amount required varies by each
194 interval, but the service of each Interval is the same. Collections of such similar intervals
195 are useful in energy and other markets involving volatile resources.

196 Repeating intervals are interesting in day-to-day interactions because they are the way
197 many services already are delivered. It is useful to be able to vary a Sequence
198 parametrically. Take, for example, classroom scheduling at a College. It is typical for class
199 schedules to use one hour intervals on Monday, Wednesday, and Friday. Classes

200 scheduled on Tuesdays and Thursdays are of 50% longer duration to establish an
201 equivalent in classroom time for classes taught on the two schedules.

202
203

Figure 4: Classroom Schedules

204 Classroom Schedule 1 shows a schedule for one hour classes. Classroom Schedule 2
205 illustrates an every hour and a half schedule for classes, with 15 minute breaks built in.

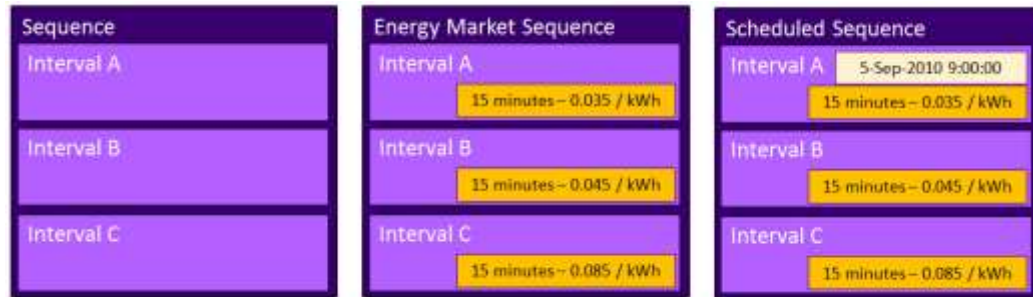

206 The duration of each Interval, and the relationship between each interval and the
207 preceding one, can be expressed within each interval using the Temporal Relationships.
208 For a regular sequence such as those in Figure 4, it is much simpler to express the
209 duration and relationship once, in the Calendar Gluon. All Intervals in the Sequence will
210 inherit those elements unless overridden.

211 **Summary**

212 WS-Calendar uses the Interval, the Sequence, and the Calendar Gluon to define
213 repeating instances of service performance. Inheritance within Sequences allows
214 parsimonious serialization as well as specific use for a variety of purposes.

215 Assembling Business Objects using WS-Calendar

216 This section provides an overview of how to build regularly recurring temporal service
217 structures using inheritance. It also discusses how to override that inheritance when you
218 need to.

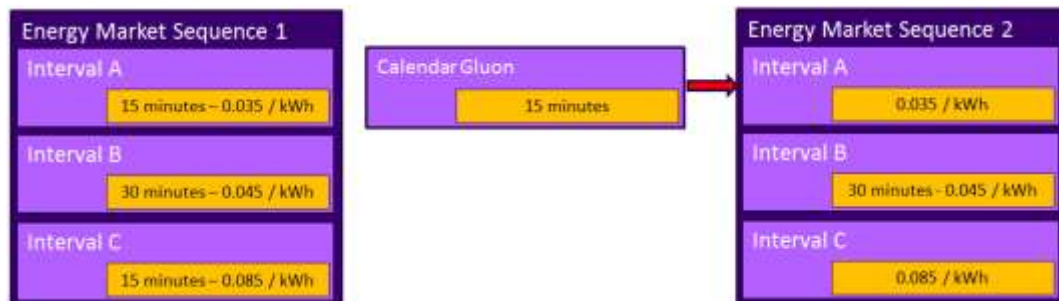

219

220

Figure 5: Building a Sequence into a Business Service

221 In Figure 5, we start with a simple Sequence. To each interval, we can add some contract
222 or service information. Finally, we schedule the Sequence by adding a single start date to
223 the whole Sequence.

224 Inheritance

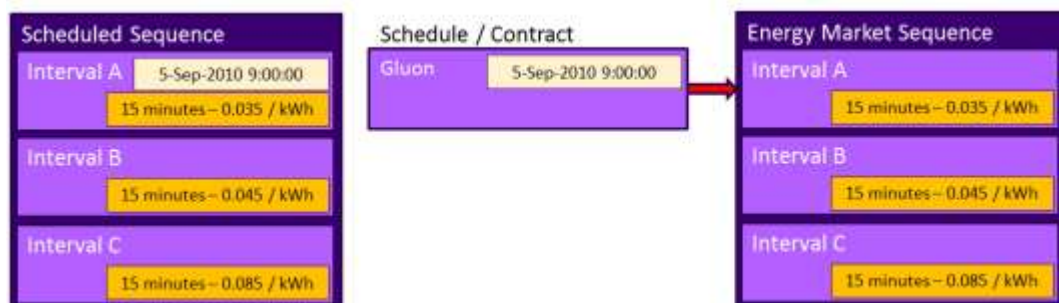

225

226

Figure 6: Inheriting Duration from an Calendar Gluon

227 We can reduce the amount of repetition using a Calendar Gluon to create a default
228 duration for the Sequence. In Figure 6, Sequence 1 and Sequence 2 are identical.

229

230

Figure 7: Inheriting Schedule from an Calendar Gluon

231 In a similar way, Figure 7 shows two identical Sequences, one inheriting a schedule from
232 an Calendar Gluon that indicates that Interval A starts at a particular date and time. Note

233 that inheritance of a Scheduling option is unique in that it sets the time only on the Interval
 234 mentioned in the Relationship. This is because all Intervals in a Sequence become
 235 scheduled when any member of the Sequence is scheduled.

236 Stacking Inheritance

237 Calendar Gluons can also be related recursively, that is, WS-Calendar supports defining a
 238 Calendar Gluon with another Calendar Gluon, and thereby with the entire sequence.

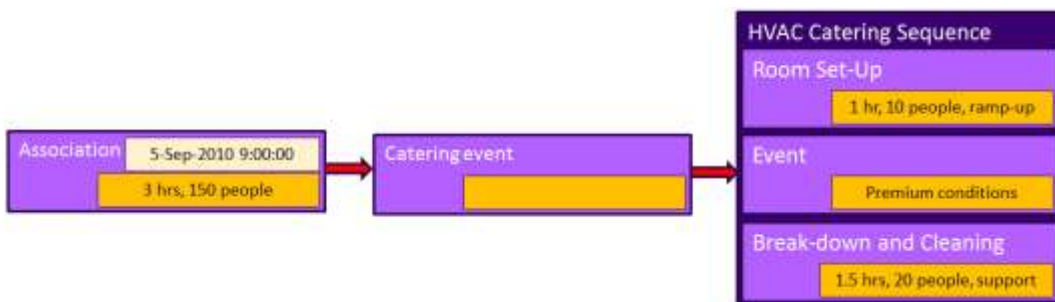

239
 240

Figure 8: Introducing Stacked Inheritance

241 In Figure 8, the Sequence is scheduled by adding a Calendar Gluon to an existing
 242 Calendar Gluon. The pre-existing Calendar Gluon defined the service offering and the
 243 default interval (15 minutes) for the Energy Market Sequence. The pre-existing Calendar
 244 Gluon also defined Interval A as the entry point for the sequence, i.e., any schedule
 245 established will be applied to Interval A.

246 This use of a Calendar Gluon enables some interesting service behaviors. A Sequence
 247 and a Calendar Gluon can define a complete service, with the entry point defined by the
 248 Gluon. We might call this service a market Offering. Another party can contract that
 249 offering by referencing the existing intact Sequence as referred to by the Calendar Gluon.
 250 In market service interactions, scheduling a service is calling for execution of a contract.
 251 Stacked inheritance enables a clean separation of product definition and market call for
 252 execution.

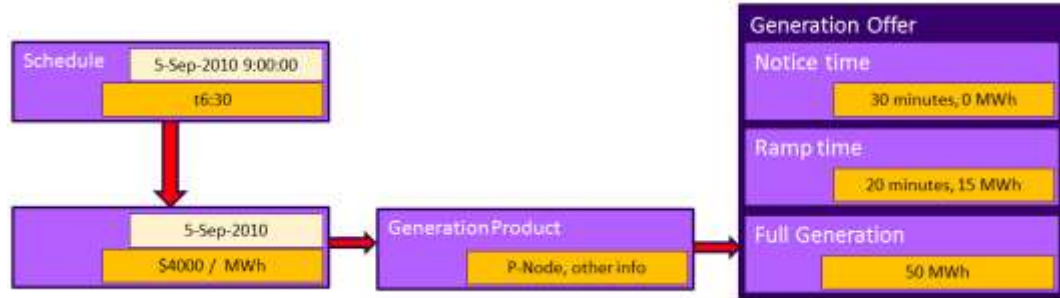

253
 254

Figure 9: Second Stacking Inheritance example

255 Figure 9 shows a different use of stacked inheritance. A catering system interacts with a
 256 standard contract for the HVAC system to support a reception in a hotel. The building
 257 system integrator created standard contracts in the Energy Management System (EMS)
 258 for those activities that are invariant. The standard contract leaves indeterminate those
 259 elements that vary for each catering job. The Sequence is assigned a name and an entry
 260 point using the Calendar Gluon.

261 At a later time, the catering software invokes this defined offering, associating the
 262 schedule and the capacity requirements to make a contract. Through inheritance, only the
 263 “Event” interval is changed, receiving a capacity (to influence ventilation) and the duration
 264 for the reception. Because the exposed Calendar Gluon indicates that the “Event” is the
 265 entry point, the reception schedule for 9:00 schedules the series so that the “Event”
 266 begins at 9:00. The catering software requires no knowledge of the support services
 267 offered in other intervals.

268 Once the contract is created, the room would show up as Busy during room set-up and
 269 break-down when standards-based calendaring inquiries are made against the EMS.

270
271

Figure 10: Stacking Calendar Gluons three deep

272 In the very similar scenario in Figure 10, an energy generation resource has market
 273 offering that requires 50 minutes of pre-notification. On September 4th, the generation
 274 resource is bid into the next day’s market with a price it is willing to accept. The market
 275 operator, schedules energy production and notifies the resource that its bid has been
 276 accepted and that its services will be required for six and a half hours.¹

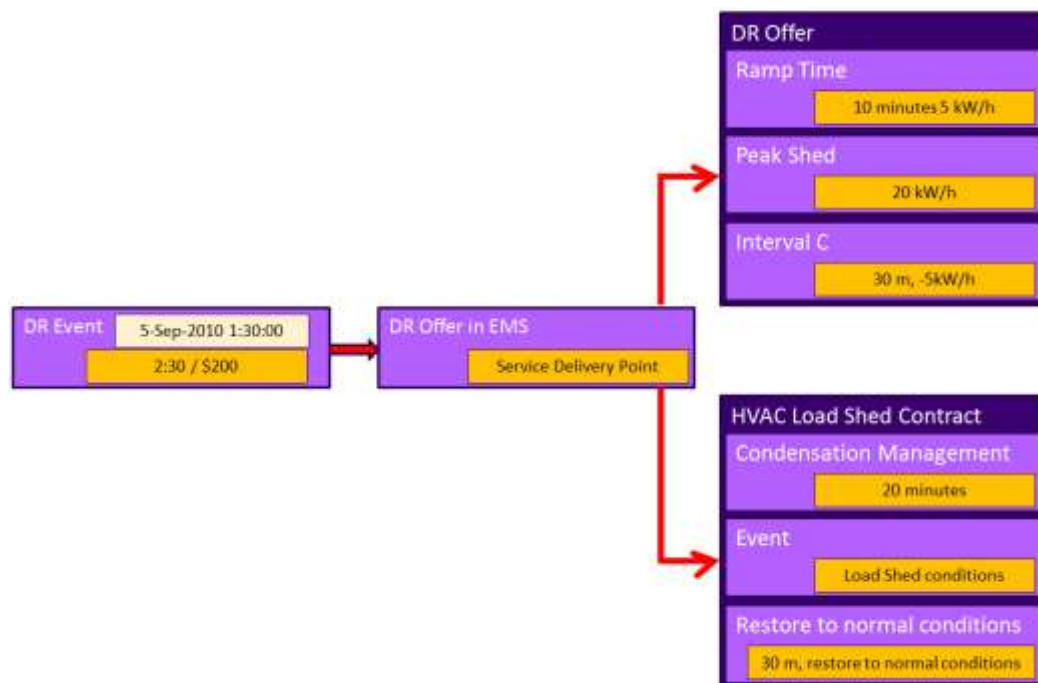

¹ Note: This is meant to be neither a depiction of today’s markets, nor a recommendation for tomorrow’s. It is merely an illustration of the capabilities and approach.

277 Advanced Scheduling

278 The examples so far have included only simple partitions and single schedules. This
279 section illustrates some of the flexibility of the WS-Calendar scheduling model

280 Multiple Relationships

281 Key interactions in smart energy involve mutually unintelligible systems coordinating their
282 behavior for the optimum economic result. Today's interactions are machine to machine
283 interactions; tomorrows will be business to business.

284

285 *Figure 11: One Calendar Gluon, Two Sequences*

286 Figure 11 illustrates an Energy Management System (EMS), which is offering demand
287 response (DR) to the grid-based markets. The building system integrator has defined the
288 Sequence to shut down certain systems, and then to restore them to full operation
289 afterwards. This is the HVAC Load Shed Contract.

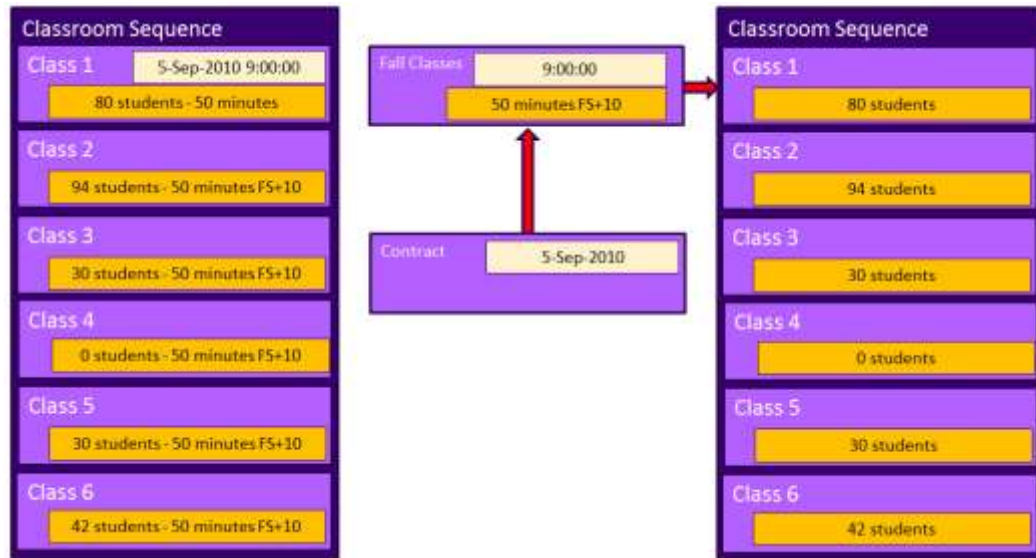

290 The energy use effect of these decisions appears in a parallel Sequence, herein the DR
291 Offer. Notice that the lead time in HVAC operation is longer than the lead time in DR—the
292 first activities of the HVAC system do not yet reduce energy use. Notice as well, that
293 during system restoration, the building will use more energy than it does during normal
294 operations, indicated by a -5kWh Demand Response.

295 When the energy supplier sends a notification of a DR Event, it schedules that event to
296 begin at 1:30 and to last for two and a half hours. This offer also comes with a monetary
297 value. When the EMS accepts the offer, it shares the DR event as scheduled with the
298 purchaser, and notifies the building systems of the three intervals in the HVAC contract as
299 scheduled.

300 Neither the EMS system nor the DR purchaser needs to have any understanding of the
301 underlying systems. Each needs merely to read the WS-Calendar based service
302 attributes.

303 Classroom Scheduling Revisited

304 We started this document with an illustration of classroom schedules rendered in WS-
305 Calendar. We now revisit this illustration using the concepts including inheritance and
306 contracts that that paper has illustrated. We started this discussion of Sequences with an
307 illustration of classroom scheduling in Figure 4.

308
309

Figure 12: Classroom Schedules Revisited

310 In Figure 12, we revisit this using the inheritance. In this high-tech classroom, there are
311 systems to warm up, and ventilation levels to be maintained to support each class. The
312 registrar's office puts out a schedule for each classroom indicating how many students will
313 be in it for each of six periods during the day.

314 The classes are not really an hour long, but are 50 minutes long with a 10 minute break
315 between classes. A Campus EMS creates a schedule with an Calendar Gluon that
316 includes a 50 minute duration and a FINISHSTART relationship with a duration of 10
317 minutes. Each day begins at 9:00. This is the standard building system contract for Fall
318 Classes.

319 To finally schedule contract performance, a Calendar Gluon referencing the Fall Classes
320 and the date for each school day during the semester is created.
