<http://docs.oasis-open.org/soa-rm/v1.0/soa-rm.html>.

#### Abstract:

This document specifies the OASIS Reference Architecture Foundation for Service Oriented Architecture (SOA-RAF). It follows from the concepts and relationships defined in the OASIS Reference Model for Service Oriented Architecture as well as work conducted in other organizations. While it remains abstract in nature, the current document describes the foundation upon which specific SOA concrete architectures can be built.

The focus of the SOA-RAF is on an approach to integrating business with the information technology needed to support it. These issues are always present but are all the more important when business integration involves crossing ownership boundaries.

The SOA-RAF follows the recommended practice of describing architecture in terms of models, views, and viewpoints, as prescribed in the ANSI/IEEE 1471-2000 (now ISO/IEC 42010-2007) Standard.

It has three main views: the *Participation in a SOA Ecosystem* view which focuses on the way that participants are part of a Service Oriented Architecture ecosystem; the *Realization of a SOA Ecosystem* view which addresses the requirements for constructing a SOA-based system in a SOA ecosystem; and the *Ownership in a SOA Ecosystem* view which focuses on what is meant to own a SOA-based system.

The SOA-RAF is of value to Enterprise Architects, Business and IT Architects as well as CIOs and other senior executives involved in strategic business and IT planning.

**Status:**

This document was last revised or approved by the OASIS Service Oriented Architecture Reference Model TC on the above date. The level of approval is also listed above.

Technical Committee members should send comments on this specification to the Technical Committee's email list. Others should send comments to the Technical Committee by using the "Send A Comment" button on the Technical Committee's web page at <http://www.oasis-open.org/committees/soa-rm/>.

For information on whether any patents have been disclosed that may be essential to implementing this specification, and any offers of patent licensing terms, please refer to the Intellectual Property Rights section of the Technical Committee web page (<http://www.oasis-open.org/committees/soa-rm/ipr.php>).

**Citation format:**

When referencing this specification the following citation format should be used:

# 1 Introduction

Service Oriented Architecture (SOA) is an architectural paradigm that has gained significant attention within the information technology (IT) and business communities. The SOA ecosystem described in this document bridges the area between business and IT. It is neither wholly IT nor wholly business, but is of both worlds. Neither business nor IT completely own, govern and manage this SOA ecosystem. Both sets of concerns must be accommodated for the SOA ecosystem to fulfill its purposes.<sup>1</sup>

The OASIS Reference Model for SOA [**SOA-RM**] provides a common language for understanding the important features of SOA but does not address the issues involved in constructing, using or owning a SOA-based system. This document focuses on these aspects of SOA.

The intended audiences of this document and expected benefits to be realized include non-exhaustively:

- Enterprise Architects - will gain a better understanding when planning and designing enterprise systems of the principles that underlie Service Oriented Architecture;
- Standards Architects and Analysts - will be able to better position specific specifications in relation to each other in order to support the goals of SOA;
- Decision Makers - will be better informed as to the technology and resource implications of commissioning and living with a SOA-based system; in particular, the implications following from multiple ownership domains; and
- Users/Developers - will gain a better understanding of what is involved in participating in a SOA-based system.

## 1.1 Context for Reference Architecture for SOA

### 1.1.1 What is a Reference Architecture?

A reference architecture models the abstract architectural elements in the domain of interest independent of the technologies, protocols, and products that are used to implement a specific solution for the domain. It differs from a reference model in that a reference model describes the important concepts and relationships in the domain focusing on what distinguishes the elements of the domain; a reference architecture elaborates further on the model to show a more complete picture that includes showing what is involved in realizing the modeled entities, while staying independent of any particular solution but instead applies to a class of solutions.

It is possible to define reference architectures at many levels of detail or abstraction, and for many different purposes. A reference architecture is not a concrete architecture; i.e., depending on the requirements being addressed by the reference architecture, it generally will not completely specify all the technologies, components and their relationships in sufficient detail to enable direct implementation.

---

<sup>1</sup> By *business* we refer to any activity that people are engaged in. We do not restrict the scope of SOA ecosystems to commercial applications.

## 33 1.1.2 What is this Reference Architecture?

34 There is a continuum of architectures, from the most abstract to the most detailed. As a Committee, we  
35 have liaised and worked with other groups and organizations working in this space to ensure that our  
36 efforts overlap as little as possible (we look at some of these other works in Appendix C). The result is  
37 that this Reference Architecture is an abstract realization of SOA, focusing on the elements and their  
38 relationships needed to enable SOA-based systems to be used, realized and owned while avoiding  
39 reliance on specific concrete technologies. This positions the work at the more abstract end of the  
40 continuum, and constitutes what is described in [TOGAF v9] as a 'foundation architecture'. It is  
41 nonetheless a *reference* architecture as it remains solution-independent and is therefore characterized as  
42 a *Reference Architecture Foundation* because it takes a first principles approach to architectural modeling  
43 of SOA-based systems.

44 While requirements are addressed more fully in Section 2, the SOA-RAF makes key assumptions that  
45 SOA-based systems involve:

- 46 • Use of resources that are distributed across ownership boundaries;
- 47 • people and systems interacting with each other, also across ownership boundaries;
- 48 • security, management and governance that are similarly distributed across ownership  
49 boundaries; and
- 50 • interaction between people and systems that is primarily through the exchange of messages with  
51 reliability that is appropriate for the intended uses and purposes.

52 Even in apparently homogenous structures, such as within a single organization, different groups and  
53 departments nonetheless often have ownership boundaries between them. This reflects organizational  
54 reality as well as the real motivations and desires of the people running those organizations.

55 Such an environment as described above is an *ecosystem* and, specifically in the context of SOA-based  
56 systems, is a **SOA ecosystem**. This concept of an ecosystem perspective of SOA is elaborated further in  
57 Section 1.2.

58 This SOA-RAF shows how Service Oriented Architecture fits into the life of users and stakeholders, how  
59 SOA-based systems may be realized effectively, and what is involved in owning and managing them.  
60 This serves two purposes: to ensure that SOA-based systems take account of the specific constraints of  
61 a SOA ecosystem, and to allow the audience to focus on the high-level issues without becoming over-  
62 burdened with details of a particular implementation technology.

## 63 1.1.3 Relationship to the OASIS Reference Model for SOA

64 The OASIS Reference Model for Service Oriented Architecture identifies the key characteristics of SOA  
65 and defines many of the important concepts needed to understand what SOA is and what makes it  
66 important. The Reference Architecture Foundation takes the Reference Model as its starting point, in  
67 particular the vocabulary and definition of important terms and concepts.

68 The SOA-RAF goes further in that it shows how SOA-based systems can be realized – albeit in an  
69 abstract way. As noted above, SOA-based systems are better thought of as dynamic systems rather than  
70 stand-alone software products. Consequently, how they are used and managed is at least as important  
71 architecturally as how they are constructed.

## 72 1.1.4 Relationship to other Reference Architectures

73 Other SOA reference architectures have emerged in the industry, both from the analyst community and  
74 the vendor/solution provider community. Some of these reference architectures are quite abstract in  
75 relation to specific implementation technologies, while others are based on a solution or technology stack.  
76 Still others use middleware technology such as an Enterprise Service Bus (ESB) as their architectural  
77 foundation.

78 As with the Reference Model, this Reference Architecture is primarily focused on large-scale distributed  
79 IT systems where the participants may be legally separate entities. It is quite possible for many aspects of  
80 this Reference Architecture to be realized on quite different platforms.

81 In addition, this Reference Architecture Foundation, as the title illustrates, is intended to provide  
82 foundational models on which to build other reference architectures and eventual concrete architectures.

83 The relationship to several other industry reference architectures for SOA and related SOA open  
84 standards is described in Appendix C.

### 85 1.1.5 Expectations set by this Reference Architecture Foundation

86 This Reference Architecture Foundation is not a complete blueprint for realizing SOA-based systems. Nor  
87 is it a technology map identifying all the technologies needed to realize SOA-based systems. It does  
88 identify many of the key aspects and components that will be present in any well designed SOA-based  
89 system. In order to actually use, construct and manage SOA-based systems, many additional design  
90 decisions and technology choices will need to be made.

## 91 1.2 Service Oriented Architecture – An Ecosystems 92 Perspective

93 Many systems cannot be completely understood by a simple decomposition into parts and subsystems –  
94 in particular when many autonomous parts of the system are governing interactions. We need also to  
95 understand the context within which the system functions and the participants involved in making it  
96 function. This is the **ecosystem**. For example, a biological ecosystem is a self-sustaining and dynamic  
97 association of plants, animals, and the physical environment in which they live. Understanding an  
98 ecosystem often requires a holistic perspective that considers the relationships between the elements of  
99 the system and their environment at least as important as the individual parts of the system.

100 This Reference Architecture Foundation views the SOA architectural paradigm from an ecosystems  
101 perspective: whereas a system will be a **capability** developed to fulfill a defined set of needs, a **SOA**  
102 **ecosystem** is a space in which people, processes and machines act together to deliver those capabilities  
103 as services.

104 Viewed as whole, a SOA ecosystem is a network of discrete processes and machines that, together with  
105 a community of people, creates, uses, and governs specific services as well as external suppliers of  
106 resources required by those services.

107 In a SOA ecosystem there may not be any single person or organization that is really ‘in control’ or ‘in  
108 charge’ of the whole although there are identifiable stakeholders who have influence within the  
109 community and control over aspects of the overall system.

110 The three key principles that inform our approach to a SOA ecosystem are:

- 111 • a SOA is a paradigm for *exchange of value* between independently acting *participants*;
- 112 • participants (and stakeholders in general) have legitimate claims to *ownership* of resources that  
113 are made available within the SOA ecosystem; and
- 114 • the behavior and performance of the participants are subject to *rules of engagement* which are  
115 captured in a series of policies and contracts.

## 116 1.3 Viewpoints, Views and Models

### 117 1.3.1 ANSI/IEEE 1471-2000:ISO/IEC 42010-2007

118 The SOA-RAF uses and follows the IEEE “Recommended Practice for Architectural Description of  
119 Software-Intensive Systems” [ANSI/IEEE 1471] and [ISO/IEC 42010]. An architectural description  
120 conforming to this standard must include the following six (6) elements:

- 121 1. Architectural description identification, version, and overview information
- 122 2. Identification of the system stakeholders and their concerns judged to be relevant to the  
123 architecture
- 124 3. Specifications of each viewpoint that has been selected to organize the representation of the  
125 architecture and the rationale for those selections
- 126 4. One or more architectural views
- 127 5. A record of all known inconsistencies among the architectural description’s required constituents
- 128 6. A rationale for selection of the architecture (in particular, showing how the architecture supports  
129 the identified stakeholders’ concerns).

130 The standard defines the following terms<sup>2</sup>:

131 **Architecture**

132 The fundamental organization of a system embodied in its components, their relationships to  
133 each other, and to the environment, and the principles guiding its design and evolution.

134 **Architectural Description**

135 A collection of products that document the architecture.

136 **System**

137 A collection of components organized to accomplish a specific function or set of functions.

138 **System Stakeholder**

139 A system stakeholder is an individual, team, or organization (or classes thereof) with interests in,  
140 or concerns relative to, a system.

141 A stakeholder's concern should not be confused with either a need or a formal requirement. A concern,  
142 as understood here, is an area or topic of interest. Within that concern, system stakeholders may have  
143 many different requirements. In other words, something that is of interest or importance is not the same  
144 as something that is obligatory or of necessity [TOGAF v9].

145 When describing architectures, it is important to identify stakeholder concerns and associate them with  
146 viewpoints to insure that those concerns are addressed in some manner by the models that comprise the  
147 views on the architecture. The standard defines views and viewpoints as follows:

148 **View**

149 A representation of the whole system from the perspective of a related set of concerns.

150 **Viewpoint**

151 A specification of the conventions for constructing and using a view. A pattern or template from  
152 which to develop individual views by establishing the purposes and audience for a view and the  
153 techniques for its creation and analysis.

154 In other words, a view is what the stakeholders see whereas the viewpoint defines the perspective from  
155 which the view is taken and the methods for, and constraints upon, modeling that view.

156 It is important to note that viewpoints are independent of a particular system (or solutions). In this way,  
157 the architect can select a set of candidate viewpoints first, or create new viewpoints, and then use those  
158 viewpoints to construct specific views that will be used to organize the architectural description. A view,  
159 on the other hand, is specific to a particular system. Therefore, the practice of creating an architectural  
160 description involves first selecting the viewpoints and then using those viewpoints to construct specific  
161 views for a particular system or subsystem. Note that the standard requires that each view corresponds to  
162 exactly one viewpoint. This helps maintain consistency among architectural views which is a normative  
163 requirement of the standard.

164 A view is comprised of one or more architectural models, where model is defined as:

165 **Model**

166 An abstraction or representation of some aspect of a thing (in this case, a system)

---

<sup>2</sup> See <http://www.iso-architecture.org/ieee-1471/cm/cm-1471-2000.html> for a diagram of the standard's Conceptual Framework

167 All architectural models used in a particular view are developed using the methods established by the  
 168 architectural viewpoint associated with that view. An architectural model may participate in more than one  
 169 view but a view must conform to a single viewpoint.

### 170 1.3.2 UML Modeling Notation

171 An open standard modeling language is used to help visualize structural and behavioral architectural  
 172 concepts. Although many architecture description languages exist, we have adopted the Unified Modeling  
 173 Language™ 2 (UML® 2) [UML 2] as the main viewpoint modeling language. Normative UML is used  
 174 unless otherwise stated but it should be noted that it can only partially describe the concepts in each  
 175 model – it is important to read the text in order to gain a more complete understanding of the concepts  
 176 being described in each section.

177 The UML presented should not be treated blindly or automatically: the models are intended to formalize  
 178 the concepts and relationships defined and described in the text but the nature of the RAF means that it  
 179 still concerns an abstract layer rather than an implementable layer.

## 180 1.4 SOA-RAF Viewpoints

181 The SOA-RAF specifies three views (described in detail in Sections 3, 4, and 5) that conform to three  
 182 viewpoints: *Participation in a SOA Ecosystem*, *Realization of a SOA Ecosystem*, and *Ownership in a SOA*  
 183 *Ecosystem*. There is a one-to-one correspondence between viewpoints and views (see Table 1).

Viewpoint Element	Viewpoint		
	Participation in a SOA Ecosystem	Realization of a SOA Ecosystem	Ownership in a SOA Ecosystem
Main concepts covered	Captures what is meant for people to participate in a SOA ecosystem.	Captures what is meant to realize a SOA-based system in a SOA ecosystem.	Captures what is meant to own a SOA-based system in a SOA ecosystem
Stakeholders addressed	All participants in the SOA ecosystem	Those involved in the design, development and deployment of SOA-based systems	Those involved in governing, managing, securing, and testing SOA-based systems
Concerns addressed	Understanding ecosystem constraints and contexts in which business can be conducted predictably and effectively.	Effective construction of SOA-based systems.	Processes to ensure governance, management, security, and testing of SOA-based systems.
Modeling Techniques used	UML class diagrams	UML class, sequence, component, activity, communication, and composite structure diagrams	UML class and communication diagrams

184 Table 1 - Viewpoint specifications for the OASIS Reference Architecture Foundation for  
 185 SOA

### 186 1.4.1 Participation in a SOA Ecosystem Viewpoint

187 This viewpoint captures a SOA ecosystem as an environment for people to conduct their business. We do  
 188 not limit the applicability of such an ecosystem to commercial and enterprise systems. We use the term  
 189 business to include any transactional activity between multiple users.

190 All stakeholders in the ecosystem have concerns addressed by this viewpoint. The primary concern for  
191 people is to ensure that they can conduct their business effectively and safely in accordance with the  
192 SOA paradigm. The primary concern of decision makers is the relationships between people and  
193 organizations using systems for which they, as decision makers, are responsible but which they may not  
194 entirely own, and for which they may not own all of the components of the system.

195 Given SOA's value in allowing people to access, manage and provide services across, we must explicitly  
196 identify those boundaries and the implications of crossing them.

## 197 **1.4.2 Realization of a SOA Ecosystem Viewpoint**

198 This viewpoint focuses on the infrastructure elements that are needed to support the construction of SOA-  
199 based systems. From this viewpoint, we are concerned with the application of well-understood  
200 technologies available to system architects to realize the SOA vision of managing systems and services  
201 that cross ownership boundaries.

202 The stakeholders are essentially anyone involved in designing, constructing and deploying a SOA-based  
203 system.

## 204 **1.4.3 Ownership in a SOA Ecosystem Viewpoint**

205 This viewpoint addresses the concerns involved in owning and managing SOA-based systems within the  
206 SOA ecosystem. Many of these concerns are not easily addressed by automation; instead, they often  
207 involve people-oriented processes such as governance bodies.

208 Owning a SOA-based system implies being able to manage an evolving system. It involves playing an  
209 active role in a wider ecosystem. This viewpoint is concerned with how systems are managed effectively,  
210 how decisions are made and promulgated to the required end points; how to ensure that people may use  
211 the system effectively; and how the system can be protected against, and recover from consequences of,  
212 malicious intent.

## 213 **1.5 Terminology**

214 The keywords "MUST", "MUST NOT", "REQUIRED" (and by extension, "REQUIRES"), "SHALL", "SHALL  
215 NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are  
216 to be interpreted as described in **[RFC2119]**.

217 References are surrounded with [square brackets and are in bold text].

218 The terms "SOA-RAF", "this Reference Architecture" and "Reference Architecture Foundation" refer to  
219 this document, while "the Reference Model" and "SOA-RM" refer to the OASIS Reference Model for  
220 Service Oriented Architecture. **[SOA-RM]**.

### 221 **Usage of Terms**

222 Certain terms are used in this document (in sections 3 to 6) to denote concepts that are formally defined  
223 here and intended to be used with the specific meanings indicated. Where mention is first made of a  
224 formally defined concept, or the term is used within the definition of another concept, we use a **bold font**.  
225 When this occurrence appears in the text substantially in advance of the formal definition, it is also  
226 **hyperlinked** to the definition in the body of the text. A list of all such terms is included in the [Index of](#)  
227 [Terms at Appendix B](#).

## 281 2 Architectural Goals and Principles

282 This section identifies the goals of this Reference Architecture Foundation and the architectural principles  
283 that underpin it.

### 284 2.1 Goals and Critical Success Factors of the Reference 285 Architecture Foundation

286 There are three principal goals:

- 287 1. to show how SOA-based systems can effectively bring participants with needs ('consumers') to  
288 interact with participants offering appropriate capabilities as services ('producers');
- 289 2. for participants to have a clearly understood level of confidence as they interact using SOA-based  
290 systems; and
- 291 3. for SOA-based systems to be scaled for small or large systems as needed.

292 There are four factors critical to the achievement of these goals:

- 293 1. **Action:** an account of participants' action within the ecosystem;
- 294 2. **Trust:** an account of how participants' internal perceptions of the reliability of others guide their  
295 behavior (i.e., the trust that participants may or may not have in others)
- 296 3. **Interaction:** an account of how participants can interact with each other; and
- 297 4. **Control:** an account of how the management and governance of the entire SOA ecosystem can  
298 be arranged.

299 These goals and success factors are expanded in the following subsections.

#### 300 2.1.1 Goals

##### 301 2.1.1.1 Effectiveness

302 A primary purpose of the SOA-RAF is to show how SOA-based systems ensure that participants can use  
303 the facilities of the system to meet their needs. This does not imply that every need has a SOA solution,  
304 but for those needs that can benefit, we look at what is needed to use the SOA paradigm effectively.

305 The key factors that govern effectiveness from a participant's perspective are actions undertaken—  
306 especially across ownership boundaries — with other participants in the ecosystem and lead to  
307 measurable results.

##### 308 2.1.1.2 Confidence

309 SOA-based systems should enable service providers and consumers to conduct their business with the  
310 appropriate level of confidence in the interaction. Confidence is especially important in situations that are  
311 high-risk; this includes situations involving multiple ownership domains as well as situations involving the  
312 use of sensitive resources.

313 Confidence has many dimensions: confidence in the successful interactions with other participants,  
314 confidence in the assessment of trust, as well as confidence that the ecosystem is properly managed.

##### 315 2.1.1.3 Scalability

316 The third goal of this reference architecture is scalability. In architectural terms, we determine scalability in  
317 terms of the smooth growth of complex systems as the number and complexity of services and  
318 interactions between participants increases. Another measure of scalability is the ease with which  
319 interactions can cross ownership boundaries.

## 320 2.1.2 Critical Success Factors

321 A critical success factor (CSF) is a property of the intended system, or a sub-goal that directly supports a  
322 goal and there is strong belief that without it the goal is unattainable. CSFs are not necessarily  
323 measurable in themselves. CSFs can be associated with more than one goal.

324 In many cases, critical success factors are often denoted by adjectives: reliability, trustworthiness, and so  
325 on. In our analysis of the SOA paradigm, however, it seems more natural to identify four critical concepts  
326 (nouns) that characterize important aspects of SOA:

### 327 2.1.2.1 Action

328 Participants' principal mode of participation in a SOA ecosystem is action; typically action in the interest of  
329 achieving some desired **real world effect**. Understanding how action is related to SOA is thus critical to  
330 the paradigm.

### 331 2.1.2.2 Trust

332 The viability of a SOA ecosystem depends on participants being able to effectively measure the  
333 trustworthiness of the system and of participants. Trust is a private assessment of a participant's belief in  
334 the integrity and reliability of the SOA ecosystem (see Section 3.2.5.1).

335 Trust can be analyzed in terms of trust in infrastructure facilities (otherwise known as reliability), trust in  
336 the relationships and effects that are realized by interactions with services, and trust in the integrity and  
337 confidentiality of those interactions particularly with respect to external factors (otherwise known as  
338 security).

339 Note that there is a distinction between trust in a SOA-based system and trust in the capabilities  
340 accessed via the SOA-based system. The former focuses on the role of SOA-based systems as a  
341 *medium* for conducting business, the latter on the trustworthiness of participants in such systems. This  
342 architecture focuses on the former, while trying to encourage the latter.

### 343 2.1.2.3 Interaction

344 In order for a SOA ecosystem to function, it is essential that the means for participants to interact with  
345 each other is available throughout the system. Interaction encompasses not only the mechanics and  
346 semantics of **communication** but also the means for discovering and offering communication.

### 347 2.1.2.4 Control

348 Given that a large-scale SOA-based system may be populated with many services, and used by large  
349 numbers of people; managing SOA-based systems properly is a critical factor for engendering confidence  
350 in them. This involves both managing the services themselves and managing the relationships between  
351 people and the SOA-based systems they are utilizing; the latter being more commonly identified with  
352 governance.

353 The governance of SOA-based systems requires decision makers to be able to set policies about  
354 participants, services, and their relationships. It requires an ability to ensure that policies are effectively  
355 described and enforced. It also requires an effective means of measuring the historical and current  
356 performances of services and participants.

357 The scope of management of SOA-based systems is constrained by the existence of multiple ownership  
358 domains.

## 359 2.2 Principles of this Reference Architecture Foundation

360 The following principles serve as core tenets that guided the evolution of this reference architecture.

### 361 Technology Neutrality

362 Statement: Technology neutrality refers to independence from particular technologies.

363 Rationale: We view technology independence as important for three main reasons: technology  
364 specific approach risks confusing issues that are technology specific with those that are  
365 integrally involved with realizing SOA-based systems; and we believe that the principles  
366 that underlie SOA-based systems have the potential to outlive any specific technologies  
367 that are used to deliver them. Finally, a great proportion of this architecture is inherently  
368 concerned with people, their relationships to services on SOA-based systems and to  
369 each other.

370 Implications: The Reference Architecture Foundation must be technology neutral, meaning that we  
371 assume that technology will continue to evolve, and that over the lifetime of this  
372 architecture that multiple, potentially competing technologies will co-exist. Another  
373 immediate implication of technology independence is that greater effort is needed on the  
374 part of architects and other decision makers to construct systems based on this  
375 architecture.

### 376 Parsimony

377 Statement: Parsimony refers to economy of design, avoiding complexity where possible and  
378 minimizing the number of components and relationships needed.

379 Rationale: The hallmark of good design is parsimony, or “less is better.” It promotes better  
380 understandability or comprehension of a domain of discourse by avoiding gratuitous  
381 complexity, while being sufficiently rich to meet requirements.

382 Implications: Parsimoniously designed systems tend to have fewer but better targeted features.

### 383 Distinction of Concerns

384 Statement: Distinction of Concerns refers to the ability to cleanly identify and separate out the  
385 concerns of specific stakeholders in such a way that it is possible to create architectural  
386 models that reflect those stakeholders’ viewpoint. In this way, an individual stakeholder or  
387 a set of stakeholders that share common concerns only see those models that directly  
388 address their respective areas of interest.

389 Rationale: As SOA-based systems become more mainstream and increasingly complex, it will be  
390 important for the architecture to be able to scale. Trying to maintain a single, monolithic  
391 architecture description that incorporates all models to address all possible system  
392 stakeholders and their associated concerns will not only rapidly become unmanageable  
393 with rising system complexity, but it will become unusable as well.

394 Implications: This is a core tenet that drives this reference architecture to adopt the notion of  
395 architectural viewpoints and corresponding views. A viewpoint provides the formalization  
396 of the groupings of models representing one set of concerns relative to an architecture,  
397 while a view is the actual representation of a particular system. The ability to leverage an  
398 industry standard that formalizes this notion of architectural viewpoints and views helps  
399 us better ground these concepts for not only the developers of this reference architecture  
400 but also for its readers. The IEEE Recommended Practice for Architectural Description of  
401 Software-Intensive Systems [ANSI/IEEE 1471], [ISO/IEC 42010] is the standard that  
402 serves as the basis for the structure and organization of this document.

### 403 Applicability

404 Statement: Applicability refers to that which is relevant. Here, an architecture is sought that is  
405 relevant to as many facets and applications of SOA-based systems as possible; even  
406 those yet unforeseen.

407 Rationale: An architecture that is not relevant to its domain of discourse will not be adopted and thus  
408 likely to languish.

409 Implications: The Reference Architecture Foundation needs to be relevant to the problem of matching  
410 needs and capabilities under disparate domains of ownership; to the concepts of ‘Intranet  
411 SOA’ (SOA within the enterprise) as well as ‘Internet SOA’ (SOA outside the enterprise);  
412 to the concept of ‘Extranet SOA’ (SOA within the extended enterprise, i.e., SOA with  
413 suppliers and trading partners); and finally, to ‘net-centric SOA’ or ‘Internet-ready SOA.’

### 3 Participation in a SOA Ecosystem View

**No man is an island**

*No man is an island entire of itself; every man  
is a piece of the continent, a part of the main;  
if a clod be washed away by the sea, Europe  
is the less, as well as if a promontory were, as  
well as any manner of thy friends or of thine  
own were; any man's death diminishes me,  
because I am involved in mankind.  
And therefore never send to know for whom  
the bell tolls; it tolls for thee.*

John Donne

The *Participation in a SOA Ecosystem* view in the SOA-RAF focuses on the constraints and context in which people conduct business using a SOA-based system. By business we mean any shared activity whose objective is to satisfy particular **needs** of each participant. To effectively employ the SOA paradigm, the architecture must take into account the fact and implications of different **ownership** domains, and how best to organize and utilize capabilities that are distributed across those different ownership domains. These are the main architectural issues that the *Participation in a SOA Ecosystem* view tries to address.

The subsections below expand on the abstract Reference Model by identifying more fully and with more specificity what challenges need to be addressed in order to successfully apply the SOA paradigm. Although this view does not provide a specific recipe, it does identify the important things that need to be considered and resolved within an ecosystem context.

The main models in this view are:

- The **SOA Ecosystem Model** introduces the main relationships between the social structure and the SOA-based System, as well as the key role played by the hybrid concept of participant in both.
- the **Social Structure in a SOA Ecosystem Model** introduces the key elements that underlie the relationships between participants and that must be considered as pre-conditions in order to effectively bring needs and capabilities together across **ownership boundaries**;
- the **Action in a SOA Ecosystem Model** introduces the key concepts involved in service **actions**, and shows how **joint action** and **real-world effect** are the target outcomes that motivate interacting in a SOA ecosystem.

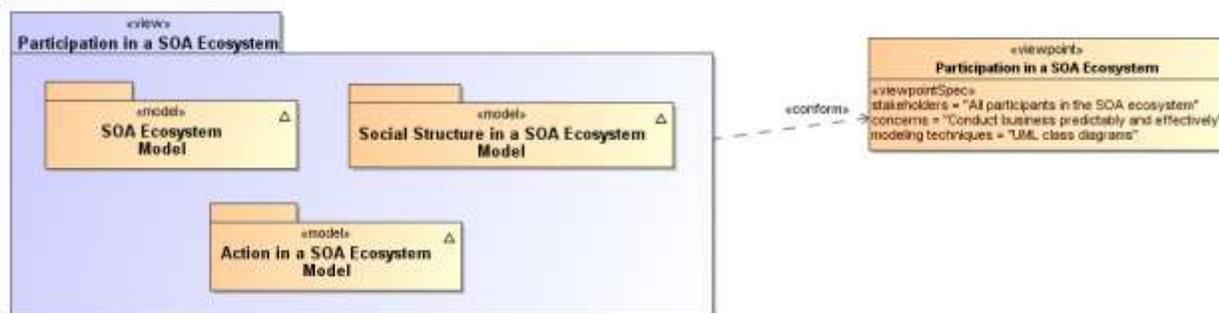

Figure 1 - Model elements described in the *Participation in a SOA Ecosystem* view

Furthermore, this *Participation in a SOA Ecosystem* view helps us understand the importance of execution context – the set of technical and business elements that allow interaction to occur in, and thus business to be conducted using, a SOA-based system.

The dominant mode of **communication** within a SOA ecosystem is electronic, supported by IT resources and artifacts. The **stakeholders** (see next section) are nonetheless people: since there is inherent indirection involved when people and systems interact using electronic means, we lay the foundations for

455 how *communication* can be used to represent and enable action. However, it is important to understand  
456 that these communications are usually a means to an end and not the primary interest of the participants  
457 of the ecosystem.

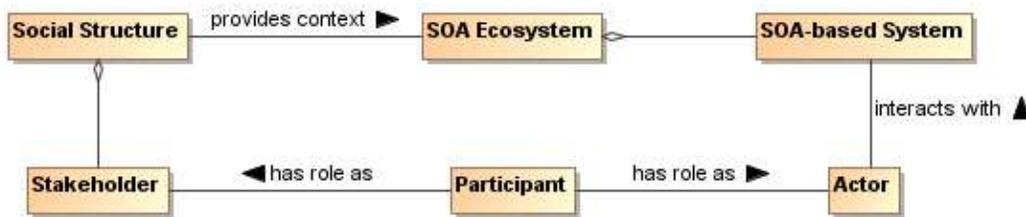

### 458 3.1 SOA Ecosystem Model

459 The OASIS SOA Reference Model defines *Service Oriented Architecture* (SOA) as “a paradigm for  
460 organizing and utilizing distributed capabilities that may be **under the control of different ownership**  
461 **domains**” (our emphasis) and *services* as “the mechanism by which needs and capabilities are brought  
462 together”. The central focus of SOA is “the task or business function – getting something done.”

463 Together, these ideas describe an environment in which business functions (realized in the form of  
464 services) address business needs. Service implementations utilize capabilities to produce specific (real  
465 world) effects that fulfill those business needs. Both those using the services, and the capabilities  
466 themselves, may be distributed across ownership domains, with different **policies** and conditions of use  
467 in force – this environment is referred to as a **SOA Ecosystem** and is modeled in *Figure 2*.

468 The role of a service in a SOA Ecosystem is to enable effective **business solutions** in this environment.  
469 Any technology system created to deliver a service in such an environment is referred to as a **SOA-**  
470 **based system**. SOA is thus a paradigm that guides the identification, design, implementation (i.e.,  
471 organization), and utilization of such services. SOA-based systems act as technology-based proxies for  
472 activity that would otherwise be carried out within and between social structures.

473 A SOA-based system is concerned with how **actors** interact within a system to deliver a specific result -  
474 the delivery of a real world effect. The SOA ecosystem is concerned with all potential stakeholders and  
475 the roles that they can play; how some stakeholders’ needs are satisfied by other stakeholders’ solutions;  
476 how stakeholders assess **risk**; how they relate to each other through policies and **contracts**; and how  
477 they communicate and establish relationships of **trust** in the processes leading to the delivery of a  
478 specific result.

479  
480 *Figure 2 - SOA Ecosystem Model*

#### 481 **SOA Ecosystem**

482 An environment encompassing one or more **social structure(s)** and **SOA-based system(s)** that  
483 interact together to enable effective **business solutions**

#### 484 **SOA-based System**

485 A technology system created to deliver a service within a **SOA Ecosystem**

486 Social Structures are defined and described in more detail in the next model, shown in *Figure 3*.

487 **Stakeholders, Actors, and Participants** are formally defined in Section 3.2.1.

488 Participants (as stakeholders and as actors), SOA-based systems, and the environment (or context)  
489 within which they all operate, taken together forms the SOA ecosystem. Participants (or their **delegates**)  
490 interact with a SOA-based system - in the role of actors - and are also members of a social structure - in  
491 the role of stakeholders. Here we explicitly note that stakeholders and, thus, participants are people<sup>3</sup>  
492 because machines alone cannot truly have a stake in the outcomes of a social structure. Delegates may  
493 be human and nonhuman but are not directly stakeholders. Stakeholders, both Participants and **Non-**  
494 **participants**, may potentially benefit from the services delivered by the SOA-based system. Again, this is  
495 discussed more fully in Section 3.2.1.

496 The SOA ecosystem may reflect the SOA-based activities within a particular enterprise or of a wider  
497 network of one or more enterprises and individuals; these are modeled in and discussed with respect to  
498 *Figure 3*. Although a SOA-based system is essentially an IT concern, it is nonetheless a system  
499 engineered deliberately to be able to function in a SOA ecosystem. In this context, a service is the  
500 mechanism that brings a SOA-based system **capability** together with stakeholder needs in the wider  
501 ecosystem.

502 Several interdependent concerns are important in our view of a SOA ecosystem. The ecosystem includes  
503 stakeholders who are participants in the development, deployment and **governance** and use of a system  
504 and its services; or who may not participate in certain activities but are nonetheless affected by the  
505 system. Actors – whether stakeholder **participants** or delegates who act only on behalf of participants  
506 (without themselves having any stake in the actions that they have been tasked to perform) – are  
507 engaged in **actions** which have an impact on the real world and whose meaning and intent are  
508 determined by implied or agreed-to semantics. This is discussed further in relation to the model in *Figure 4*  
509 and elaborated more fully in Section 3.3.

## 510 3.2 Social Structure in a SOA Ecosystem Model

511 The Social Structure Model explains the relationships between stakeholders and the social context in  
512 which they operate, within and between distinct boundaries. It is also the foundation for understanding  
513 **security**, governance and management in the SOA ecosystem.

514 Actions undertaken by people (whether natural or legal persons) are performed in a *social context* that  
515 defines the relationships between them. That context is provided by **social structures** existing in society  
516 and the roles played by each person as stakeholders in those structures.

517 Whether informal peer groups, communities of practice, associations, enterprises, corporations,  
518 government agencies, or entire nations, these structures interact with each other in the world, using  
519 treaties, contracts, market rules, handshakes, negotiations and – when necessary – have recourse to  
520 arbitration and legislation. They interact because there is a mutual benefit in doing so: one has something  
521 that the other can provide. They interact across defined or implicit **ownership boundaries** that define the  
522 limits of one structure (and the limits of its **authority**, responsibilities, capabilities, etc.) and the beginning  
523 of another.

524 Social structures, together with their **constitution**, their stakeholders, their mission and goals, need  
525 therefore to be understood when examining the role that technology plays. Technology systems play an  
526 increasing role in carrying out many of the functions performed by such structures and therefore model  
527 real-world procedures. The technology systems serve as proxies in digital space for these real-world  
528 structures and procedures. The SOA paradigm is particularly concerned with designing, configuring and

---

<sup>3</sup> 'People' and 'person' must be understood as both humans and 'legal persons', such as companies, who have **rights** and **responsibilities** similar to 'natural persons' (humans)

529 managing such systems across ownership boundaries precisely because this mirrors the real-world  
 530 interactions between discrete structures and across their ownership boundaries.

531 A stakeholder in a social structure will be involved in many 'actions' that do not involve a SOA-based  
 532 system. Although such actions and the roles relating to them are outside the scope of this Reference  
 533 Architecture Foundation, they may nonetheless result in constraining or otherwise impacting a given SOA  
 534 ecosystem – for example, a new item of legislation that regulates service interactions. The terms **Actor**  
 535 and **Action** used throughout the document refer thus only to SOA-based systems.

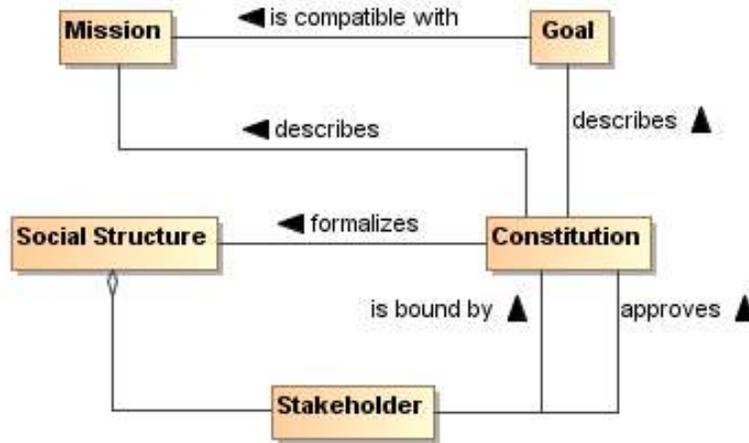

Figure 3 - Social Structure Model

536  
 537  
 538 **Social Structure**

539 A nexus of relationships amongst people brought together for a specific purpose, the structure's  
 540 mission.

541 The social structure is established with an implied or explicitly defined mission, usually reflected in the  
 542 goals laid down in the social structure's constitution or other 'charter'. Although goals are often expressed  
 543 in terms of general ambitions for the social structure's work or of desired end states, objectives are  
 544 expressed more formally in terms of specific, measurable, and achievable action required to realize those  
 545 states. Action in the context of a social structure is discussed in Section 3.3.

546 A social structure may involve any number of persons as stakeholders and a large number of different  
 547 relationships may exist among them. The organizing principle for these relationships is the social  
 548 structure's mission. Any given person can be a stakeholder in multiple social structures and a social  
 549 structure itself can be a stakeholder in its own right as part of a larger one or in another social structure  
 550 entirely. These multiple roles can result in disagreements, particularly when the mission or goals of  
 551 different social structures do not align.

552 A social structure can take different forms. An enterprise is a common kind of social structure with its  
 553 distinct legal personality; an online community group might represent a social structure of peers that is  
 554 very loose, albeit with a shared mission. A market represents a social structure of buyers and sellers.  
 555 Legislation in different geo-political areas (from local and regional to national or global) provides a  
 556 framework in which social structures can operate.

557 A social structure will further its goals in one of two ways:

- 558 • by acting alone, using its own **resources**;
- 559 • interacting with other structures and using their resources.

560 Many interactions take place within social structures. Some interactions may or may not cross ownership  
 561 boundaries depending on the scale and internal organization of the structure (an enterprise, for example,  
 562 can itself be composed of sub-enterprises). Our focus is on interactions *between* social structures,  
 563 particularly as they determine the way that technology systems need to interact. Systems that are  
 564 designed to do this are SOA-based systems.

565 The nature and extent of the interactions that take place will reflect, often implicitly, degrees of trust  
 566 between people and the very specific circumstances of each person at the time, and over the course, of

567 their interactions. It is in the nature of a SOA ecosystem that these relationships are rendered more  
568 explicit and are formalized as a central part of what the **[SOA-RM]** refers to as Execution Context.

569 The validity of the interactions between social structures is not always clear and is often determined  
570 ultimately by relevant legislation. For example, when a customer buys a book over the Internet, the  
571 validity of the transaction may be determined by the place of incorporation of the book vendor, the  
572 residence of the buyer, or a combination of both. Such legal jurisdiction qualification is typically buried in  
573 the fine print of the service description.

#### 574 **Constitution**

575 A set of **rules**, written or unwritten, that formalize the mission, goals, scope, and functioning of a  
576 **social structure**.

577 Every social structure functions according to **rules** by which people interact with each other within the  
578 structure. In some cases, this is based on an explicit agreement; in other cases, participants behave as  
579 though they agree to the constitution without a formal agreement. In still other cases, participants abide  
580 by the rules with some degree of reluctance. In all cases, the constitution may change over time; in those  
581 cases of implicit agreement, the change can occur quickly. Section 5.1 contains a detailed discussion of  
582 governance and SOA.

### 583 **3.2.1 Stakeholders, Participants, Actors and Delegates**

584 A social structure represents the interests of a collection of people who have **rights** and **responsibilities**  
585 within the structure. People have a 'stake' in such a social structure, and when that social structure is part  
586 of a SOA Ecosystem, the people continue to interact through their roles as stakeholders. In addition,  
587 people – either directly or through their delegates - interact with SOA-based (technology) systems. Here,  
588 the people interact through their roles as actors interacting with specific system-level activity.

589 A person who participates in a social structure as a stakeholder *and* interacts with a SOA-based system  
590 as an actor is defined as an ecosystem **Participant**. The concept of participant is particularly important as  
591 it reflects a hybrid role of a Stakeholder concerned with expressing needs and seeing those needs fulfilled  
592 *and* an Actor directly involved with system-level activity that result in necessary effects.

593 The hybrid role of Participant provides a bridge between social structures within the wider (real-world)  
594 ecosystem – in particular the world of the stakeholder – and the more specific (usually technology-  
595 focused) system – the world of the actor.

596 The concept of the ecosystem therefore embraces all aspects of the 'real world', human-centered, social  
597 structures that are concerned with business interactions together with the technology-centered SOA-  
598 based system that deliver services:

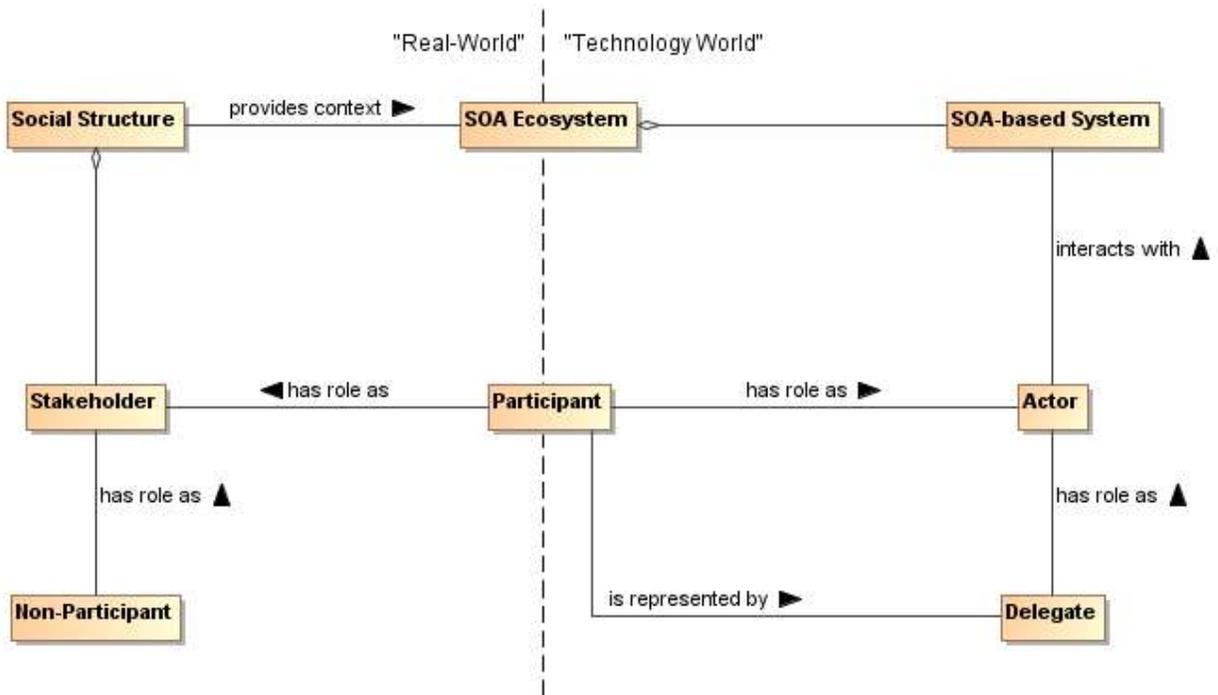

Figure 4 – Stakeholders, Actors, Participants and Delegates

599  
600  
601

### Stakeholder

A person with an interest (a 'stake') in a **social structure**.

602 Not all stakeholders necessarily participate in all activities in the SOA ecosystem; indeed, the interest of  
603 non-participant stakeholders may be to realize the benefits of a well-functioning ecosystem and not suffer  
604 unwanted consequences. Non-participant stakeholders cannot all or always be identified in advance but  
605 due account is often taken of such stakeholder types, including potential customers, beneficiaries, and  
606 other affected third parties. A stakeholder may be a participant with respect to some activities and a non-  
607 participant with respect to others.  
608

### Actor

A role played either by a **Participant** or its **Delegate** and that interacts with a **SOA-based system**.

### Participant

A person who plays a role *both* in the **SOA ecosystem** as a **stakeholder** and with the **SOA-based system** as an **actor** either

- directly, in the case of a human participant; or
- indirectly, via a **delegate**.

617 Not all participants are necessarily benign to the social structure: such 'negative stakeholders' might  
618 deliberately seek a negative impact on the ecosystem (such as hackers or criminals) and social structures  
619 will work to ensure that they are not able to operate as welcome participants.

### Non-Participant

A person who plays no role as a **participant** in a **social structure's** activities but nonetheless has an interest in, or is affected by, such activities.

### Delegate

A role played by a human or an automated or semi-automated agent and acting on behalf of a **participant** but not directly sharing the participant's stake in the outcome.

623  
624  
625

626 Many actors interact with a SOA-based system, including software agents that permit people to offer, and  
627 interact with, services; delegates that represent the interests of other participants; or security agents  
628 charged with managing the security of the ecosystem. Note that automated agents are *always* delegates,  
629 in that they act on behalf of a participant.

630 In the different models of the SOA-RAF, the term actor is used when action is being considered at the  
631 level of the SOA-based system and when it is not relevant who is carrying out the action. However, if the  
632 actor is acting explicitly *on behalf of* a participant, then we use the term delegate. This underlines the  
633 importance of delegation in SOA-based systems, whether the delegation is of work procedures carried  
634 out by human agents who have no stake in the actions with which they are tasked but act on behalf of a  
635 participant who does; or whether the delegation is performed by technology (automation). On the other  
636 hand, if it is important to emphasize that when the actor is also a stakeholder in the ecosystem, then we  
637 use the term participant. This also underlines the pivotal role played by a participant, in a unique position  
638 between the social structure and the SOA-based system, in the broader ecosystem.

639 The difference between a participant and a delegate is that a delegate acts on behalf of a participant and  
640 must have the authority to do so. Because of this, every social structure must clearly define the roles  
641 assigned to actors (whether participants or delegates) in carrying out activity within its domain.

## 642 **3.2.2 Social Structures and Roles**

643 Social structures are abstractions: they cannot directly perform actions with SOA-based systems – only  
644 actors can, whether they be participants acting under their own volition or delegates (human or not)  
645 simply following the instructions of participants. An actor advances the objectives of a social structure  
646 through its interaction with SOA-based systems, influencing actions that deliver results. The specifics of  
647 the interaction depend on the roles defined by the social structure that the actor may assume or have  
648 conferred and the nature of the relationships between the stakeholders concerned. These relationships  
649 can introduce constraints on an actor when engaged in an action. These points are illustrated in *Figure 5*.

650 A role is not immutable and is often time-bound. An actor can have one or more roles concurrently and  
651 may change them over time and in different contexts, even over the course of a particular interaction.

### 652 **3.2.2.1 Authority, Rights, and Responsibilities**

653 One participant with appropriate authority in the social structure may formally designate a role for a  
654 delegate or another participant, with associated rights and responsibilities, and that authority may even  
655 qualify a period during which the designated role may be valid. In addition, while many roles are clearly  
656 identified, with appropriate names and definitions of responsibilities, it is also possible to separately  
657 bestow rights, bestow or assume responsibilities and so on, often in a temporary fashion. For example,  
658 when a company president delegates certain responsibilities on another person, this does not imply that  
659 the other person has become company president. Likewise, a company president may bestow on  
660 someone else her role during a period of time that she is on vacation or otherwise unreachable with the  
661 understanding that she will re-assume the role when she returns from vacation.

662 Conversely, someone who exhibits qualification and skill may assume a role without any formal  
663 designation. For example, an office administrator who has demonstrated facility with personal computers  
664 may be known as (and thus assumed to role of) the ‘go to’ person for people who need help with their  
665 computers.

666 The social structure is responsible for establishing the authority by which actors carry out actions in line  
667 with defined constraints:

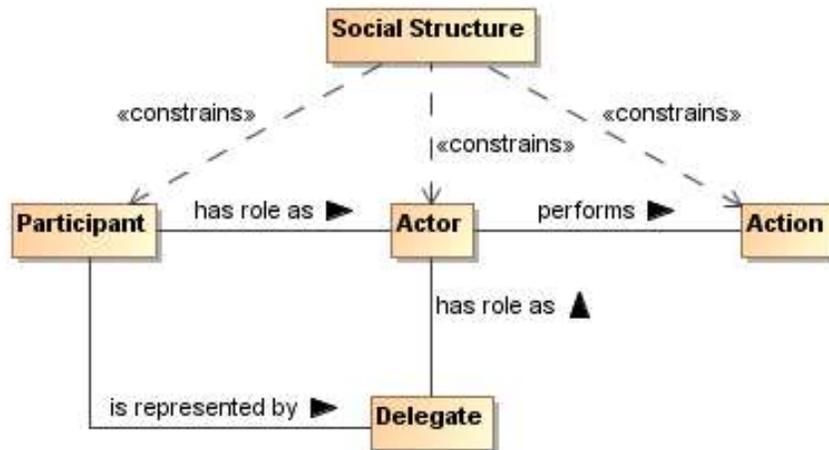

Figure 5 - Social Structures, Roles and Action

668  
669

670 **Authority**

671 A **right** conferred on a **participant** to ensure that **actions** are carried out consistent with the  
672 objectives of a **social structure**.

673 Actions are carried out by actors, either participants themselves or delegates acting on their behalf, by  
674 interacting with the SOA-based system.

675 **Right**

676 A predetermined **permission** conferred upon an **actor** to perform some **action** or assume a role  
677 in relation to the **social structure**.

678 Rights can be constrained. For example, sellers might have a general right to refuse service to potential  
679 customers but this right could be constrained so as to be exercised only when certain criteria are met.

680 **Responsibility**

681 A predetermined **obligation** on a **participant** to ensure that some **action** is performed or assume  
682 a role in relation to other **participants**.

683 Responsibility implies human agency and thus aligns with participants and potentially human delegates  
684 but not with nonhuman delegates. This applies even if the consequences of such responsibility can  
685 impact other (human and non-human) actors. Having authority often implies having responsibility.

686 Rights, authorities, responsibilities and roles form the foundation for the security model as well as  
687 contributing to the governance model in the **Ownership in a SOA Ecosystem** View of the SOA-RAF.

688 **3.2.2.2 Permissions and Obligations**

689 People will assume and perform roles according to their actual or perceived rights and responsibilities,  
690 with or without explicit authority. In the context of a SOA ecosystem, human abilities and skills are  
691 relevant as they equip individuals with knowledge, information and tools that may be necessary to have  
692 meaningful and productive interactions with a view to achieving a desired outcome. For example, a  
693 person who wants a particular book, and has both the right and responsibility of purchasing the book from  
694 a given bookseller, will not have that need met from the online delegate of that bookstore if he does not  
695 know how to use a web browser. Equally, just because someone does have the requisite knowledge or  
696 skills does not entitle them *per se* to interact with a specific system.

697 Assuming or accepting rights and responsibilities depend on two important types of constraints that are  
698 relevant to a SOA ecosystem: Permission and Obligation.

699 **Permission**

700 A constraint that identifies **actions** that an **actor** is (or is not) allowed to perform and/or the  
701 **states** in which the actor is (or is not) permitted.

702 Note that permissions are distinct from ability, which refers to whether an actor has the capacity to  
703 perform the action. Permission does not always involve acting on behalf of anyone, nor does it imply or  
704 require the capacity to perform the action.

705 **Obligation**

706 A constraint that prescribes the **actions** that an **actor** must (or must not) perform and/or the  
707 **states** the actor must (or must not) attain or maintain.

708 An example of obligations is the case where the service **consumer** and **provider** (see below) have  
709 entered into an agreement to provide and consume a service such that the consumer is obligated to pay  
710 for the service and the provider is obligated to provide the service – based on the terms of the contract.

711 An obligation can also be a **requirement** to maintain a given **state**. This may range from a requirement to  
712 maintain a minimum balance on an account to a requirement that a service provider ‘remember’ that a  
713 particular service consumer is logged in.

714 Both permissions and obligations can be identified ahead of time, but only permissions can be validated a  
715 priori: before the intended action or before entering the constrained state. Obligations can only be  
716 validated a posteriori through some form of auditing or verification process.

717 **3.2.2.3 Service Roles**

718 As in roles generally, a participant can play one or more in the SOA ecosystem, depending on the  
719 context. A participant may be playing a role of a service provider in one relationship while simultaneously  
720 playing the role of a consumer in another. Roles inherent to the SOA paradigm include **Consumer**,  
721 **Provider**, **Owner**, and **Mediator**.

722 **Provider**

723 A role assumed by a **participant** who is offering a service.

724 **Consumer**

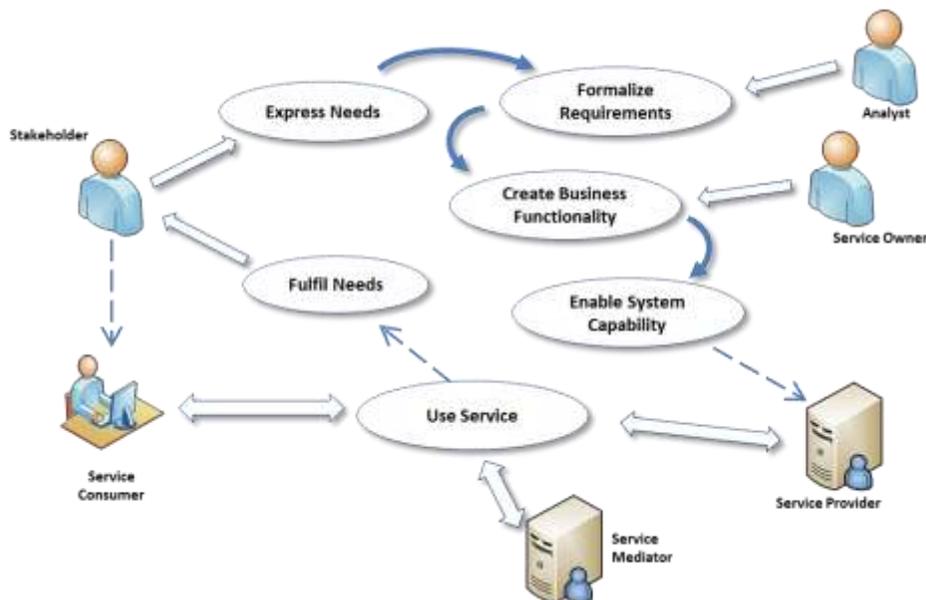

725 A role assumed by a **participant** who is interacting with a service in order to fulfill a **need**.

726 **Mediator**

727 A role assumed by a **participant** to facilitate interaction and connectivity in the offering and use of  
728 services.

729 **Owner**

730 A role assumed by a **participant** who is claiming and exercising **ownership** over a service.

731

732

Figure 6 - Roles in a Service

733 Service consumers typically initiate interactions, but this is not necessarily true in all situations.  
734 Additionally, several stakeholders may be involved in a service interaction supporting a given consumer.

735 The roles of service provider and service consumer are often seen as symmetrical, which is also not  
736 entirely correct. A stakeholder tends to express a **Need** in non-formal terms: "I want to buy that book".  
737 The type of need that a service is intended to fulfill has to be formalized and encapsulated by designers  
738 and developers as a **Requirement**. This Requirement should then be reflected in the target service, as a  
739 **Capability** that, when accessed via a service, delivers a **Real World Effect** to an arbitrary consumer:  
740 "The chosen book is ordered for the consumer." It thus fulfills the need that has been defined for an  
741 archetypal consumer.

742 Specific and particular customers may not experience a need exactly as captured by the service: "I don't  
743 want to pay that much for the book", "I wanted an eBook version", etc. There can therefore be a process  
744 of implicit and explicit negotiation between the consumer and the service, aimed at finding a 'best fit'  
745 between the consumer's specific need and the capabilities of the service that are available and consistent  
746 with the service provider's offering. This process may continue up until the point that the consumer is able  
747 to accept what is on offer as being the best fit and finally 'invokes' the service. 'Execution context' has  
748 thus been established. Conditions and agreements that contribute to the execution context are discussed  
749 throughout this Reference Architecture.

750 Service mediation by a participant can take many forms and may invoke and use other services in order  
751 to fulfill such mediation. For example, it might use a service registry in order to identify possible service  
752 partners; or, in our book-buying example, it might provide a price comparison service, suggest alternative  
753 suppliers, different language editions or delivery options.

### 754 3.2.3 Needs, Requirements and Capabilities

755 Participants in a SOA ecosystem often need other participants to *do* something, leveraging a **capability**  
756 that they do not themselves possess. For example, a customer requiring a book may call upon a service  
757 provider to deliver the book. Likewise, the service provider requires the customer to pay for it.

758 There is a reason that participants are engaged: they have different **needs** and have or apply different  
759 capabilities for satisfying them. These are core to the concept of a service. The SOA-RM defines a  
760 service as "the mechanism by which needs and capabilities are brought together". This idea of services  
761 being a mechanism 'between' needs and capabilities was introduced in order to emphasize capability as  
762 the notional or existing **business functionality** that would address a well-defined need. Service is  
763 therefore the *implementation* of such business functionality *such that it is accessible* through a well-  
764 defined interface. A capability that is isolated (i.e., it is inaccessible to potential consumers) is  
765 emphatically not a service.

#### 766 **Business Functionality**

767 A defined set of business-aligned tasks that provide recognizable business value to consumer  
768 **stakeholders** and possibly others in the **SOA ecosystem**.

769 The idea of a service in a SOA ecosystem combines business functionality with implementation, including  
770 the artifacts needed and made available as IT resources. From the perspective of software developers, a  
771 SOA service enables the use of capabilities in an IT context. For the consumer, the service (combining  
772 business functionality and implementation) generates intended real world effects. The consumer is not  
773 concerned with the underlying artifacts which make that delivery possible.

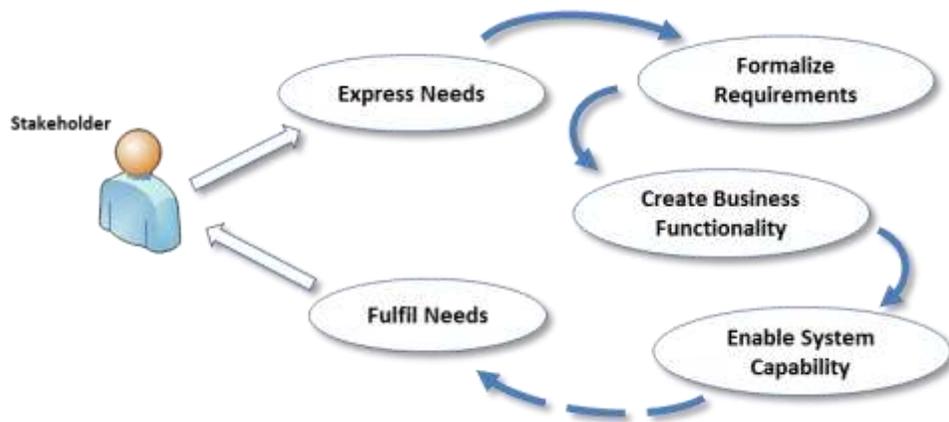

Figure 7 - Cycle of Needs, Requirements, and Fulfillment

774  
775  
776  
777  
778  
779  
780  
781  
782  
783

In a SOA context, the stakeholder expresses a need (for example, the consumer who states “I want to buy a book”) and looks to an appropriate service to fulfill that need and assesses issues such as the trustworthiness, intent and **willingness** of a particular provider. This ecosystem communication continues up to the point when the stakeholder is ready to act. The stakeholder will then interact with a provider by invoking a service (for example, by ordering the book using an online bookseller) and engaging in relevant actions with the system (at this point, in a role as an *actor*, interacting with the system through a browser or mobile device, validating the purchase, submitting billing and delivery details) with a view to achieving the desired real world effect (having the book delivered).

784 **Need**

A general statement expressed by a **stakeholder** of something deemed necessary.

786 A need may be formalized as one or more requirements that must be fulfilled in order to achieve a stated goal.

788 **Requirement**

A formal statement of a desired result (a **real world effect**) that, if achieved, will satisfy a **need**.

790 This requirement can then be used to create a capability that in turn can be brought to bear to satisfy that need. Both the requirement and the capability to fulfill it are expressed in terms of desired real world effect.

793 **Capability**

An ability to deliver a **real world effect**.

795 The Reference Model makes a distinction between a capability (as a *potential* to deliver the real world effect) and the ability of bringing that capability to bear (via a realized service) as the realization of the real world effect.

798 **Real World Effect**

A measurable change to the **shared state** of pertinent entities, relevant to and experienced by specific **stakeholders** of an **ecosystem**.

801 This implies measurable change in the overall state of the SOA ecosystem. In practice, however, it is specific state changes of certain entities that are relevant to particular participants that constitute the real world effect as experienced by those participants.

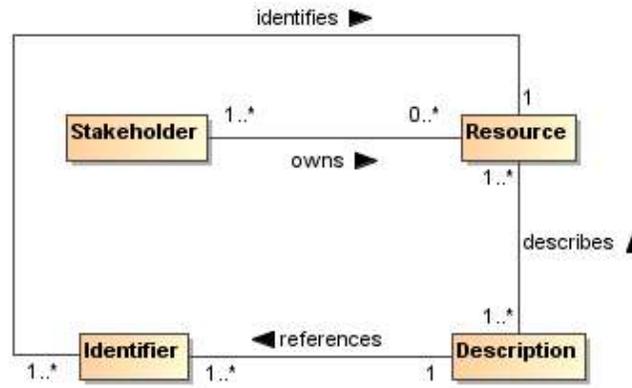

804 Objectives refer to real world effects that participants believe are achievable by a specific action or set of actions that deliver appropriate changes in shared state, as distinct from a more generally stated ‘goal’. For example, someone may wish to have enough light to read a book. In order to satisfy that goal, the reader walks over to flip a light switch. The *objective* is to change the state of the light bulb, by turning on the lamp, whereas the *goal* is to be able to read. The *real world effect* is more light being available to enable the person to read.

810 While an effect is any measurable change resulting from an action, a SOA ecosystem is concerned more specifically with real world effects.

## 812 3.2.4 Resource and Ownership

### 813 3.2.4.1 Resource

814 A resource is generally understood as an asset: it has value to someone. Key to this concept in a SOA  
815 ecosystem is that a resource must be identifiable.

816  
817

Figure 8 - Resources

#### 818 Resource

819 An identifiable entity that has value to a **stakeholder**.

820 A resource may be identifiable by different methods but within a SOA ecosystem a resource must have at  
821 least one well-formed identifier that may be unambiguously resolved to the intended resource.

822 Codified (but not *implied*) contracts, policies, obligations, and permissions are all examples of resources,  
823 as are capabilities, services, service descriptions, and SOA-based systems. An *implied* policy, contract,  
824 obligation or permission would not be a resource, even though it may have value to a stakeholder,  
825 because it is not an identifiable entity.

#### 826 Identifier

827 A sequence of characters that unambiguously indicates a particular **resource**.

828 Identifiers are assigned by social structures according to context, policies and procedures considered  
829 sufficient for that structure's purposes.

830 For example, a group of otherwise unrelated humans are all, in a given context, employees of a particular  
831 company and managed there as human resources. That company's policy is to assign each employee a  
832 unique identifier number and has processes in place to do this, including verifying documentary evidence  
833 (such as a birth certificate or ID). Each set of policies and procedures will reflect the needs of the social  
834 structure for its particular context. Resources are typically used or managed by different stakeholder  
835 groups, each of which may need to identify those resources in some particular way. As such, a given  
836 resource may have multiple identifiers, each valid for a different context. In a SOA ecosystem, it is good  
837 practice to use globally unique identifiers (for example, Internationalized Resource Identifiers, or IRIs)  
838 irrespective of any other resource identifier that might be in use for a particular context.

839 The ability to identify a resource is important in interactions to determine such things as rights and  
840 authorizations, to understand what functions are being performed and what the results mean, and to  
841 ensure repeatability or characterize differences with future interactions. Many interactions within a SOA  
842 ecosystem take place across ownership boundaries. Identifiers provide the means for all resources  
843 important to a given SOA-based system to be *unambiguously* identifiable at any moment and in any  
844 interaction.

845 Resources frequently have descriptions and the descriptions themselves may be considered resources.  
846 This is discussed in Section 4.1.1. Resource description may link to other resources and their  
847 descriptions; for example, a service description may link to a policy that constrains the conditions of use  
848 of the service.

### 849 3.2.4.2 Ownership

850 Ownership is defined as a relationship between a stakeholder and a resource, where some stakeholder  
851 (in a role as owner) has certain claims with respect to the resource.

852 Typically, the ownership relationship is one of control: the owner of a resource can control some aspect of  
853 the resource.

#### 854 Ownership

855 A set of claims, expressed as **rights** and **responsibilities** that a **stakeholder** has in relation to a  
856 **resource**; it may include the right to transfer that ownership, or some subset of rights and  
857 responsibilities, to another entity.

858 To own a resource implies taking responsibility for creating, maintaining and, if it is to be available to  
859 others, provisioning the resource. More than one stakeholder may own different rights or responsibilities  
860 associated with a given service, such as one stakeholder having the responsibility to deploy a capability  
861 as a service, another owning the rights to the profits that result from charging consumers for using the  
862 service, and yet another owning the right to use the service. There may also be joint ownership of a  
863 resource, where the rights and responsibilities are shared.

864 A stakeholder who owns a resource may delegate some or all of these rights and responsibilities to  
865 others, but typically retains the responsibility to see that the delegated rights and responsibilities are  
866 exercised as intended

867 A crucial property that distinguishes ownership from a more limited right to use is the right to transfer  
868 rights and responsibilities totally and irrevocably to another. When participants use but do not own a  
869 resource, they may not be allowed to transfer the right to use the resource to a third participant. The  
870 owner of the resource maintains the rights and responsibilities of being able to authorize others to use the  
871 owned resource.

872 Ownership is defined in relation to the social structure relative to which the given rights and  
873 responsibilities are exercised. For example, there may be constraints on how ownership may be  
874 transferred, such as a government may not permit a corporation to transfer assets to a subsidiary in a  
875 different jurisdiction.

#### 876 Ownership Boundary

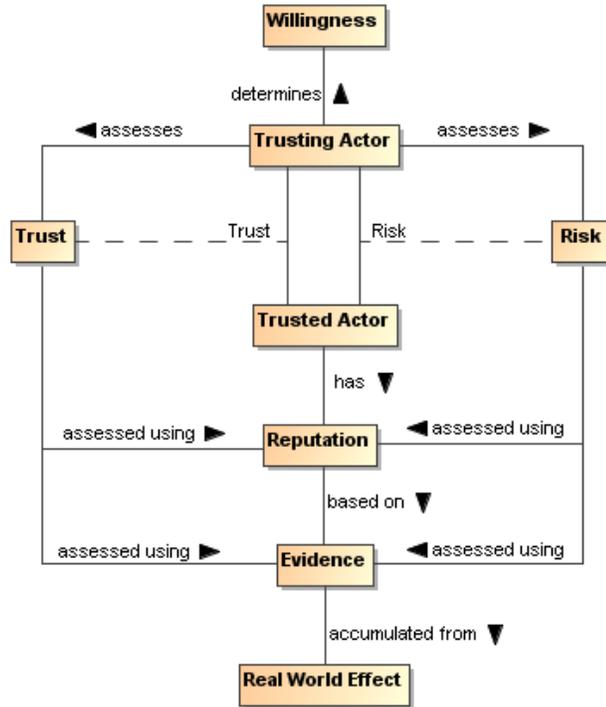

877 The extent of **ownership** asserted by a **stakeholder** or a **social structure** over a set of  
878 **resources** and for which **rights** and **responsibilities** are claimed and (usually) recognized by  
879 other stakeholders.

### 880 3.2.5 Establishing Execution Context

881 In a SOA ecosystem, providers and consumers of services may be, or may be acting on behalf of,  
882 different owners, and thus the interaction between the provider and the consumer of a given service may  
883 necessarily cross an ownership boundary. It is important to identify these ownership boundaries in a SOA  
884 ecosystem and successfully crossing them in a key aspect of establishing execution context. This is turn  
885 requires that the elements identified in the following sections be addressed.

886 **3.2.5.1 Trust and Risk**

887 For an interaction to occur each actor must be able and **willing** to participate.

888  
889 *Figure 9 - Willingness and Trust*

890 **Willingness**

891 The internal commitment of a human **actor** (or of an automated non-human agent acting on a  
892 **participant's** behalf) to carry out its part of an interaction.

893 Willingness to interact is not the same as a willingness to perform requested actions, however. For  
894 example, a service provider that rejects all attempts to perform a particular action may still be fully willing  
895 and engaged in interacting with the consumer. Important considerations in establishing willingness are  
896 both **trust** and **risk**.

897 **Trust**

898 The private assessment or internal perception of one **actor** that another actor will perform  
899 **actions** in accordance with an assertion regarding a desired **real world effect**.

900 **Risk**

901 The private assessment or internal perception of the likelihood that certain undesirable **real world**  
902 **effects** will result from **actions** taken and the consequences or implications of such.

903 Trust is involved in all interactions and each actor will play a role as either (or alternately) a 'trusting' actor  
904 and a 'trusted' actor. These roles are needed in order that all actors can trust all others in any given  
905 interaction, at least to the extent required for continuance of the interaction. The degree and nature of that  
906 trust is likely to be different for each actor, most especially when those actors are in different ownership  
907 boundaries.

908 An actor perceiving risk may take actions to mitigate that risk. At one extreme this will result in a refusal to  
909 interact. Alternately, it may involve adding protection – for example by using encrypted communication  
910 and/or anonymization – to reduce the perception of risk. Often, standard procedures are put in place to  
911 increase trust and to mitigate risk.

912

913 The assessments of trust and risk are based on evidence available to the *trusting* actor. In general, the  
914 trusting actor will seek evidence directly from the *trusted* actor (e.g., via documentation provided via the  
915 service description) as well as evidence of the reputation of the trusted actor (e.g., third-party annotations  
916 such as consumer feedback).

917 Trust is based on the confidence that the trusting actor has accurately and sufficiently gathered and  
918 assessed evidence to the degree appropriate for the situation being assessed.

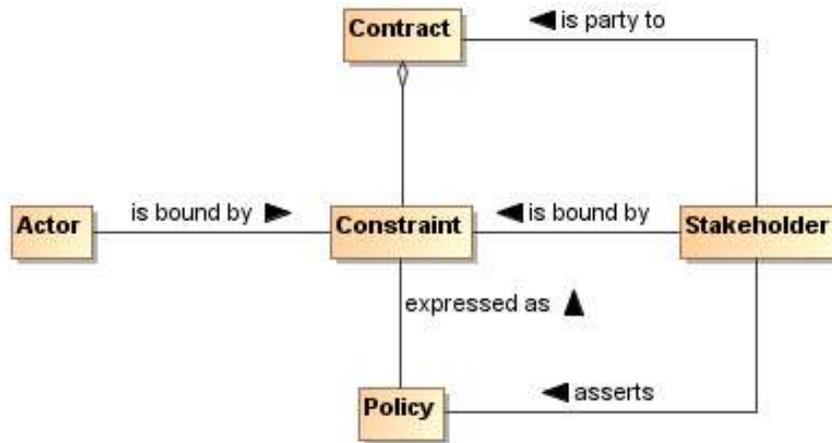

919 Assessment of trust is rarely binary. An actor is not completely trusted or untrusted because there is  
920 typically some degree of uncertainty in the accuracy or completeness of the evidence or the assessment.  
921 Similarly, there may be uncertainty in the amount and potential consequences of risk.

922 The relevance of trust to interaction depends on the assessment of risk. If there is little or no perceived  
923 risk, or the risk can be covered by another party who accepts responsibility for it, then the degree of trust  
924 may be less or not relevant in assessing possible actions. For example, most people consider there to be  
925 an acceptable level of risk to privacy when using search engines, and submit queries without any sense  
926 of trust being considered.

927 As perceived risk increases, the issue of trust becomes more of a consideration. For interactions with a  
928 high degree of risk, the trusting actor will typically require stronger or additional evidence when evaluating  
929 the balance between risk and trust. An example of high-risk is where a consumer's business is dependent  
930 on the provider's service meeting certain availability and security requirements. If the service fails to meet  
931 those requirements, the service consumer will go out of business. In this example, the consumer will look  
932 for evidence that the likelihood of the service not meeting the performance and security requirements is  
933 extremely low.

### 934 3.2.5.2 Policies and Contracts

935 As noted in the Reference Model, a policy represents some commitment and/or constraint advertised and  
936 enforced by a stakeholder and that stakeholder alone. A contract, on the other hand, represents an  
937 agreement by two or more participants. Enforcement of contracts may or may not be the responsibility of  
938 the parties to the agreement but is usually performed by a stakeholder in the ecosystem (public authority,  
939 legal system, etc.).

940  
941 *Figure 10 – Policies, Contracts and Constraints*

#### 942 Policy

943 An expression of constraints made by a **stakeholder** that the stakeholder commits to uphold and,  
944 if desired or necessary, enforce. The constraints are usually stated as **permissions** and  
945 **obligations** that affect the behavior of stakeholders or of any **actor** acting on their behalf.

946 Policies have an **owner** – the stakeholder who asserts and takes responsibility for the policy. This owner  
947 may or may not be the owner of the object of the policy. These constraints may affect the stakeholder  
948 asserting the policy or any other stakeholder involved. The constraints themselves represent some  
949 measurable limitation on the state or behavior of the object of the policy, or of those who interact with it.

## 950 **Contract**

951 An agreement made by two or more **participants** (the contracting parties) on a set of conditions  
952 (or contractual terms) together with a set of constraints that govern their behavior and/or **state** in  
953 fulfilling those conditions.

954 A service provider's policy may become a service provider/consumer contract when a service consumer  
955 agrees to the provider's policy. That agreement may be formal, or may be informal. If a consumer's policy  
956 and a provider's policy are mutually exclusive, then some form of negotiation (involving human  
957 interactions) or mediation must resolve the mutual exclusion before the service consumer/provider  
958 interaction can occur. Note that this also applies if the consumer instead of the provider introduces the  
959 policy.

960 Both policies and contracts imply a desire to see constraints respected and enforced. Stakeholders are  
961 responsible for ensuring that any constraints in the policy or contract are enforced, although the actual  
962 enforcement may be delegated to a different mechanism. A contract does not necessarily oblige the  
963 contracting parties to act (for example to use a service) but it does constrain how they act if and when the  
964 condition covered by the contract occurs (for example, when a service is invoked and used).

965 The realization of policies and contracts is discussed in Section 4.4 and contracts in the context of  
966 management are discussed in Section 5.3.4.

## 967 **3.2.5.3 Communication**

### 968 **Communication**

969 A process involving the exchange of information between a sender and one or more recipients  
970 and that ideally culminates in mutual understanding between them.

971 A communication involves a message, a sender of the message and at least one intended recipient, who  
972 must be able to correctly interpret the message – or at least those parts of the message relevant to  
973 sender and recipient in the particular context. Each must perform its respective role in order for the  
974 communication to be successful and failing which, communication is not effective.

975 A communication may involve any number of recipients. In some situations, the sender may not be aware  
976 of the recipient. However, without both a sender and a recipient, there is no communication. A given  
977 communication can be a simple one-way transmission and not require a response by the recipient.  
978 However, interaction does, necessarily, involve communication.

979 Message interpretation can itself be characterized in terms of **semantic engagement**: the proper  
980 understanding of a message in a given context.

981 We can characterize the necessary modes of interpretation in terms of a shared understanding of a  
982 common vocabulary (or mediation among vocabularies) and of the purpose of the communication. More  
983 formally, we can say that a communication has a combination of message and purpose.

984 In a SOA ecosystem, senders and recipients can be stakeholders, participants or actors, depending on  
985 whether execution context is being established or a specific interaction with the SOA-based system is in  
986 progress. Communications need not resemble human speech: indeed system-level machine-to-machine  
987 communication is typically highly stylized in form. It may take a particular form and involve terms not  
988 found in everyday human communication.

## 989 **3.2.5.4 Semantics and Semantic Engagement**

990 Shared understanding is vital to a trusted and effective ecosystem and is a prerequisite to joint action  
991 being carried out as intended. Semantics are therefore pervasive throughout SOA ecosystems and  
992 important in communications as described above, as well as a driver for policies and other aspects of the  
993 ecosystem.

994 In order to arrive at a shared understanding [wherever this is necessary within the ecosystem](#), a  
995 message's recipient must effectively understand and process statements, made in the sender's message,  
996 in a manner appropriate and sufficient to the particular context. Within a SOA-based system, non-human  
997 actors must at least be able to parse a message correctly (syntax) and act on the message's statements  
998 in a manner consistent with the sender's intent.

999 Understanding and interpreting those assertions in a SOA-based system allows all the actors in any  
1000 particular joint action to ‘know’ what may be expected of them. An actor can potentially ‘understand’ an  
1001 assertion in a number of ways, but it is specifically the process of arriving at a *shared* understanding that  
1002 is important in the ecosystem. This process is semantic engagement and it takes place in different forms  
1003 throughout the SOA ecosystem. It can be instantaneous or progressively achieved. Participants – who  
1004 play the role both as actors in the SOA-based system and as stakeholders in social structures and the  
1005 wider ecosystem – can be pivotal in resolving problems of understanding and determining when there is a  
1006 level of engagement appropriate and sufficient to the particular context.

### 1007 **Semantic Engagement**

1008           The process by which an **actor** engages with a set of assertions based on that actor’s  
1009           interpretation and understanding of those assertions.

1010 Different actors have differing capabilities and requirements for understanding assertions. This is true for  
1011 both human and non-human actors. For example, a purchase order process does not require that a  
1012 message forwarding agent ‘understand’ the purchase order, but a processing agent does need to  
1013 ‘understand’ the purchase order in order to know what to do with the order once received.

1014 The impact of any assertion can only be fully understood in terms of specific social contexts that  
1015 necessarily include the actors that are involved. For example, a policy statement that governs the actions  
1016 relating to a particular resource may have a different impact or purpose for the participant that owns the  
1017 resource than for the actor that is trying to access it: the former understands the purpose of the policy as  
1018 a statement of enforcement - the latter understands it as a statement of constraint.

## 1019 **3.3 Action in a SOA Ecosystem Model**

1020 Participants cannot always achieve desired results by leveraging resources in their own ownership  
1021 domain. This unfulfilled need leads them to seek and leverage services provided by other participants and  
1022 using resources beyond their ownership and control. The participants identify service providers with which  
1023 they think they can interact to achieve their objective and engage in joint action with those other actors  
1024 (service providers) in order to bring about the desired outcome. The SOA ecosystem provides the  
1025 environment in which this happens.

1026 An action model is put forth a-priori by the service provider, and is effectively an undertaking by the  
1027 service provider that the actions – identified in the action model and invoked consistent with the process  
1028 model – will result in the described real world effect. The action model describes the actions leading to a  
1029 real-world effect. A potential service consumer – who is interested in a particular outcome to satisfy their  
1030 need – must understand those actions as capable of achieving that desired outcome.

1031 When the consumer ‘invokes’ a service, a joint action is started as identified in the action model,  
1032 consistent with the temporal sequence as defined by the process model, and where the consumer and  
1033 the provider are the two parties of the joint action. Additionally, the consumer can be assured that the  
1034 identified real-world effects will be accomplished through evidence provided via the service description.

1035 Since the service provider does not know about all potential service consumers, the service provider may  
1036 also describe what additional constraints are necessary in order for the service consumer to invoke  
1037 particular actions, and thus participate in the joint action. These additional constraints, along with others  
1038 that might not be listed, are preconditions for the joint action to occur and/or continue (as per the process  
1039 model), and are referred to in the SOA-RM as execution context. Execution context goes all the way from  
1040 human beings involved in aligning policies, semantics, network connectivity and communication  
1041 protocols, to the automated negotiation of security protocols and end-points as the individual actions  
1042 proceed through the process model.

1043 Also, it is important to note that both actions and real world effect are recursive in nature, in the sense  
1044 that they can often be broken down into more and more granularity depending on how they are examined  
1045 and what level of detail is important.

1046 All of these things are important to getting to the core of participants’ concern in a SOA ecosystem: the  
1047 ability to leverage resources or capabilities to achieve a desired outcome, and in particular where those  
1048 resources or capabilities do not belong to them or are beyond their direct control. i.e., that are outside of  
1049 their ownership boundary.

1050 In order to use such resources, participants must be able to identify their own needs; state those needs in  
1051 the form of requirements; compose or identify a suitable business solution using resources or capabilities  
1052 that will meet their needs; and engage in joint action – the coordinated set of actions that participants  
1053 pursue in order to achieve measurable results in furtherance of their goals.

1054 In order to act in a way that is appropriate and consistent, participants must communicate with each other  
1055 about their own goals, objectives and policies, and those of others. This is the main concern of Semantic  
1056 Engagement.

1057 A key aspect of joint action revolves around the trust that both parties must exhibit in order to participate  
1058 in the joint action. The willingness to act and a mutual understanding of both the information exchanged  
1059 and the expected results is the particular focus of Sections 3.2.5.1 and 3.2.5.4.

### 1060 **3.3.1 Services Reflecting Business**

1061 The SOA paradigm often emphasizes the interface through which service interaction is accomplished.  
1062 While this enables predictable integration in the sense of traditional software development, the prescribed  
1063 interface alone does not guarantee that services will be composable into business solutions.

#### 1064 **Business Solution**

1065 A set of defined interactions that combine implemented or notional **business functionality** in  
1066 order to address a set of business needs.

#### 1067 **Composability**

1068 The ability to combine individual services, each providing defined **business functionality**, so as  
1069 to provide more complex **business solutions**.

1070 To achieve composability, capabilities must be identified that serve as building blocks for business  
1071 solutions. In a SOA ecosystem, these building blocks are captured as services representing well-defined  
1072 business functions, operating under well-defined policies and other constraints, and generating well-  
1073 defined real world effects. These service building blocks should be relatively stable so as not to force  
1074 repeated changes in the compositions that utilize them, but should also embody SOA attributes that  
1075 readily support creating compositions that can be varied to reflect changing circumstances.

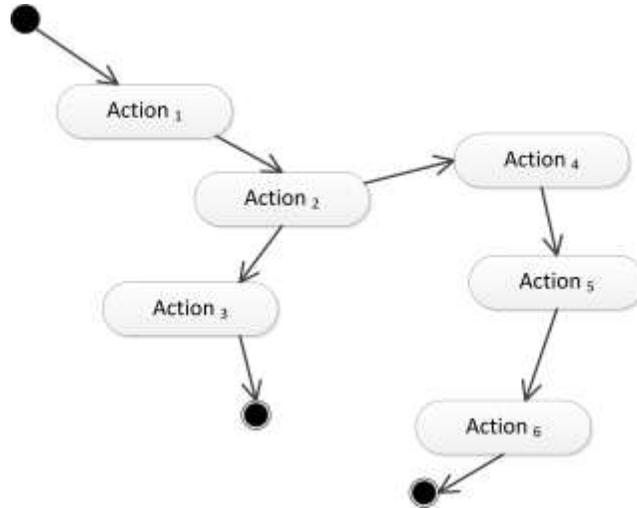

1076 The SOA paradigm emphasizes both composition of services and opacity of how a given service is  
1077 implemented. With respect to opacity, the SOA-RM states that the service could carry out its described  
1078 functionality through one or more automated and/or manual processes that in turn could invoke other  
1079 available services.

1080 Any composition can itself be made available as a service and the details of the business functionality,  
1081 conditions of use, and effects are among the information documented in its service description.

1082 Composability is important because many of the benefits of a SOA approach assume multiple uses for  
1083 services, and multiple use requires that the service deliver a business function that is reusable in multiple  
1084 business solutions. Simply providing a Web Service interface for an existing IT artifact does not, in  
1085 general, create opportunities for sharing business functions. Furthermore, the use of tools to auto-  
1086 generate service software interfaces will not guarantee services that can effectively be used within  
1087 compositions if the underlying code represents programming constructs rather than business functions. In  
1088 such cases, services that directly expose the software details will be as brittle to change as the underlying  
1089 code and will not exhibit the characteristic of loose coupling.

1090 **3.3.2 Activity, Action, and Joint Action**

1091 In general terms, entities act in order to fulfill particular objectives. More precisely, they generate activity.  
1092 An activity is made up of specific Actions (or other Activities) and is formally defined in [ISO/IEC 10746-2]  
1093 as “a single-headed directed acyclic graph of actions...”<sup>4</sup> It is most clearly understood diagrammatically:

1094 *Figure 11: An Activity, expressed informally as a graph of Actions, with a single Start*  
1095 *point and alternative End points*  
1096

1097 What constitutes an Action or an Activity will be a matter of context. For the SOA-RAF, an Action  
1098 represents the smallest and most discrete activity that must be modeled for a given Viewpoint.

1099 The form of Activity that is of most interest within a SOA ecosystem is that involving Actions as defined  
1100 below and their interaction across ownership boundaries (and thus involving interaction between more  
1101 than one actor) – we call this **joint action**. In Figure 12 below, one line of activity (on the left) can be  
1102 completed thru Action<sub>3</sub> without crossing any ownership boundary but the alternative path, starting at  
1103 Action<sub>4</sub>, can only be completed as a result of joint action across an ownership boundary:

---

<sup>4</sup> See [ISO/IEC 10746] Part 2: Foundations

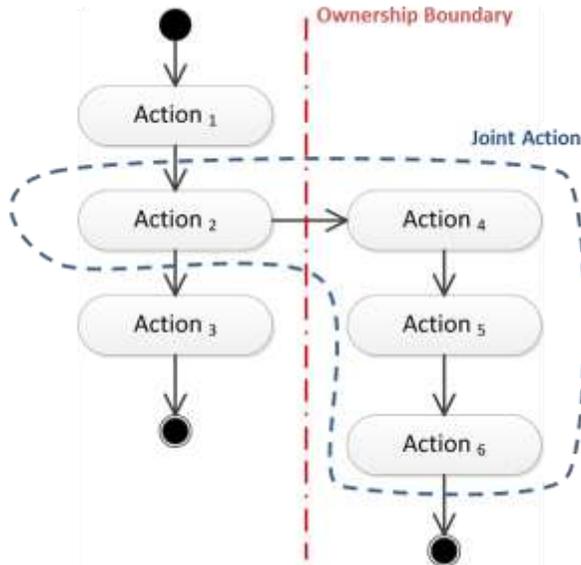

Figure 12: Activity involving Actions across an ownership boundary

1104  
1105

1106 **Action**

1107 The application of intent by an **actor** to cause an effect.

1108 The aspect of action that distinguishes it from mere force or accident is that someone *intends* that the  
1109 action achieves a desired objective or effect. This definition of action is very general. In the case of SOA,  
1110 we are mostly concerned with actions that take place within a system and have specific effects on the  
1111 SOA ecosystem – defined in section 3.2.3 as real world effects. The actual real world effect of an action,  
1112 however, may go beyond the intended effect.

1113 In order for multiple actors to participate in a joint action, they must each act according to their role within  
1114 the joint action. This is achieved through communication and messaging.

1115 Communication – the formulation, transmission, receipt and interpretation of messages – is the  
1116 foundation of all joint actions within the SOA ecosystem, given the inherent separation – often across  
1117 ownership boundaries – of actors in the system.

1118 Communication between actors requires that they play the roles of ‘sender’ or ‘receiver’ of messages as  
1119 appropriate to a particular action – although it is not necessarily required that they both be active  
1120 simultaneously.

1121 An actor sends a message in order to communicate with other actors. The communication itself is often  
1122 not intended as part of the desired real world effect but rather includes messages that seek to establish,  
1123 manage, monitor report on, and guide the joint action throughout its execution.

1124 Like communication, joint action usually involves different actors. However, joint action – resulting from  
1125 the deliberate actions undertaken by different actors – *intentionally* impacts shared state within the  
1126 system leading to real world effects.

1127 **Joint Action**

1128 The coordinated set of **actions** involving the efforts of two or more **actors** to achieve an effect.

1129 Note that the effect of a joint action is *not* always equivalent to one or more effects of the individual  
1130 actions of the actors involved, i.e., it may be more than the sum of the parts.

1131 Different perspectives lead to either communication or joint action as being considered most important.  
1132 For example, from the perspective of ecosystem security, the integrity of the communications may be  
1133 dominant; from the perspective of ecosystem governance, the integrity of the joint action may be  
1134 dominant.

### 1135 3.3.3 State and Shared State

#### 1136 State

1137 The condition of an entity at a particular time.

1138 State is characterized by a set of facts that is true of the entity. In principle, the total state of an entity (or  
1139 the world as a whole) is unbounded. In practice, we are concerned only with a subset of the state of an  
1140 entity that is measurable and useful in a given context.

1141 For example, the total state of a light bulb includes the temperature of the filament of the bulb, the  
1142 composition of the glass, the dirt that is on the bulb's surface and so on. However, someone needing  
1143 more light to read is only interested in whether the bulb is 'on' or 'off' and if it is working properly. That  
1144 individual's characterization of the state of the bulb reduces to the fact: "bulb is now on".

1145 In a SOA ecosystem, there is a distinction between the set of facts about an entity that only that entity can  
1146 access and the set of facts that may be accessible to others, notably actors in the SOA-based system.

#### 1147 Private State

1148 That part of an entity's **state** that is knowable by, and accessible to, only that entity.

#### 1149 Shared State

1150 That part of an entity's **state** that is knowable by, and may be accessible to, other actors.

1151 Note that shared state does not imply that the state *is* accessible to other actors. It simply refers to that  
1152 subset of state that *may* be accessed by other actors. This will principally be the case when actors need  
1153 to participate in joint actions.

1154 It is the aggregation of the shared states of pertinent entities that constitutes the desired effect of a joint  
1155 action. Thus the change to this shared state is what is experienced in the wider ecosystem as a real world  
1156 effect

## 1157 3.4 Architectural Implications

### 1158 3.4.1 Social structures

1159 A SOA ecosystem's participants are organized into various forms of social structure. Not all social  
1160 structures are hierarchical: a SOA ecosystem **SHOULD** be able to incorporate peer-to-peer forms of  
1161 organization as well as hierarchic structures. In addition, it **SHOULD** be possible to identify and manage  
1162 any constitutional agreements that define the social structures present in a SOA ecosystem.

- 1163 • Different social structures have different rules of engagement but predictable behavior is one of  
1164 the underpinnings of trust. Mechanisms **MUST** therefore be available to:
  - 1165 ○ express constitutions and other organizing principles of participants;
  - 1166 ○ inherit rules of engagement from parent to child social structures.
- 1167 • Social structures have roles and members and this impacts who may be authorized to act and in  
1168 what circumstances. Mechanisms **MUST** be available to:
  - 1169 ○ identify and manage members of social structures
  - 1170 ○ Identify and manage attributes of the members
  - 1171 ○ describe roles and role adoption
- 1172 • Social structures overlap and interact, giving rise to situations in which rules of engagement may  
1173 conflict. In addition, a given actor may be a member of multiple social structures and the social  
1174 structures may be associated with different jurisdictions. Mechanisms **MUST** be available to:
  - 1175 ○ identify the social structures that are active during a series of joint actions;
  - 1176 ○ identify and resolve conflicts and inconsistencies.

### 1177 3.4.2 Resource and Ownership

1178 Communication about and between, visibility into, and leveraging of resources requires the unambiguous  
1179 identification of those resources. Mechanisms **MUST** be available for:

- 1180 • Assigning and guaranteeing uniqueness of globally unique identifiers

- 1181 • Identifying the extent of the enterprise over which the identifier must be understandable and
- 1182 unique
- 1183 • Ensuring the longevity of identifiers (i.e., they cannot just change arbitrarily)

### 1184 3.4.3 Policies and Contracts

- 1185 • Policies are expressed as constraints:
  - 1186 ○ Policies **MUST** be expressed
  - 1187 ○ Constraints **MUST** be enforceable
  - 1188 ○ Management of potentially large numbers of policies **MUST** be achievable
- 1189 • Policies have owners:
  - 1190 ○ Policies **SHOULD** be established by social structures.
- 1191 • Policies may not be consistent with one another:
  - 1192 ○ Policy conflict resolution techniques **MUST** exist and be in place
- 1193 • Agreements are accepted constraints:
  - 1194 ○ Contracts **SHOULD** be enforced by mechanisms of the social structure

### 1195 3.4.4 Communications as a Means of Mediating Action

1196 Using message exchange for mediating action implies

- 1197 • The structure of messages **MUST** be validated by:
  - 1198 ○ Identifying the syntax of the message;
  - 1199 ○ Identifying the vocabularies used in the communication
  - 1200 ○ Identifying the higher-level structure of the communication, such as policy assertion,
  - 1201 contract enforcement, etc.
- 1202 • A principal objective of communication is to mediate action, therefore:
  - 1203 ○ Messages **SHOULD** convey actions and events
  - 1204 ○ Receiving a message is an action, but is not the same action as the action conveyed by
  - 1205 the message
  - 1206 ○ Actions are associated with objectives of the actors involved
    - 1207 ▪ Explicit representation of objectives may facilitate automated processing of
    - 1208 messages
  - 1209 ○ An actor agreeing to adopt an objective becomes responsible for that objective

### 1210 3.4.5 Semantics

1211 Semantics is pervasive in a SOA ecosystem. There are many forms of utterance that are relevant to the

1212 ecosystem: apart from communicated content there are mission and policy statements, goals, objectives,

1213 descriptions, and agreements which are all forms of utterance.

1214 The operation of the SOA ecosystem is significantly enhanced if

- 1215 • A careful distinction is made between public semantics and private semantics. In particular, it
- 1216 **MUST** be possible for actors to process content such as communications, descriptions and
- 1217 policies solely on the basis of the public semantics of those utterances.
- 1218 • A well founded semantics **MUST** ensure that any assertions essential to the operator of the
- 1219 ecosystem (such as policy statements, and descriptions) have carefully chosen written
- 1220 expressions and associated decision procedures.
- 1221 • The role of vocabularies as a focal point for multiple actors to be able to understand each other is
- 1222 critical. While no two actors can fully share their interpretation of elements of vocabularies, they
- 1223 **SHOULD** be able to understand the intended public meaning of vocabularies' elements.

### 1224 3.4.6 Trust and Risk

1225 In traditional systems, the balance between trust and risk is achieved by severely restricting interactions

1226 and by controlling the participants of a system.

1227 Actors **MUST** be able to explicitly reason about both trust and risk in order to effectively participate in a

1228 SOA ecosystem. The more open and public the SOA ecosystem is, the more important it is for actors to

1229 be able to reason about their participation.

1230 **3.4.7 Needs, Requirements and Capabilities**

1231 In the process of capturing needs as requirements, and the subsequent requirements decomposition and  
1232 allocation processes need to be informed by capabilities that already exist.

- 1233
- Architecture **MUST** take into account existing capabilities available as services

1234 **3.4.8 The Importance of Action**

1235 Participants participate in a SOA ecosystem in order to have their needs met. This involves action; both  
1236 individual actions and joint actions.

1237 Any architectural realization of a SOA ecosystem **SHOULD** address:

- 1238
- How actions are modeled:
    - Identifying the performer or agent of the action;
    - the target of the action; and the
    - verb of the action.

1242 Any explicit models of joint action **SHOULD** take into account

- 1243
- The possible compositions that define the joint action.
  - The potential for multiple joint actions to be layered on top of each other
- 1244

## 4 Realization of a SOA Ecosystem view

*Make everything as simple as possible but no simpler.*  
Albert Einstein

The *Realization of a SOA Ecosystem* view focuses on elements that are needed to support the discovery of and interaction with services. The key questions asked are "What are services, what support is needed and how are they realized?"

The models in this view include the Service Description Model, the Service Visibility Model, the Interacting with Services Model, and the Policies and Contracts Model.

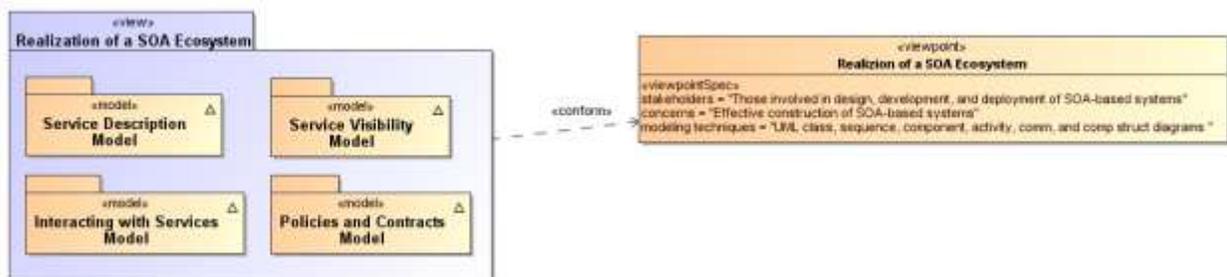

Figure 13 - Model Elements Described in the Realization of a SOA Ecosystem view

The Service Description Model informs the participants of what services exist and the conditions under which they can be used. The Policies and Contracts Model elaborates on the conditions under which service use is prescribed and agreements among participants in the SOA ecosystem.. The information in the service description as augmented by details of policy provides the basis for visibility as defined in the SOA Reference Model and captured in the Service Visibility Model. Finally, the process by which services are used under the defined conditions and agreements is described in the Interacting with Services Model.

### 4.1 Service Description Model

A service description is an artifact, often document-based, that defines or references the information needed to use, deploy, manage and otherwise control a service. This includes not only the information and behavior models associated with a service that define interaction via the service interface but also includes information needed to decide whether the service is appropriate for the current requirements of the service consumer. Thus, the service description should also include information such as service reachability, service functionality, and the policies associated with a service.

A service description artifact may be a single document or it may be an interlinked set of documents. For the purposes of this model, differences in representation are to be ignored, but the implications of a 'web of documents' are discussed later in this section.

There are several points to note regarding service description:

- The Reference Model states that one of the hallmarks of SOA is the large amount of associated description. The model presented below focuses on the description of services but it is equally important to consider the descriptions of the consumer, other participants, and needed resources other than services.
- Descriptions are inherently incomplete but may be determined as *sufficient* when it is possible for the participants to access and use the described services based only on the descriptions provided. This means that, at one end of the spectrum, a description along the lines of "That service on that machine" may be sufficient for the intended audience. On the other extreme, a service description with a machine-process-able description of the semantics of its **operations** and real world effects may be required for services accessed via automated service discovery and planning systems.

- 1285
- 1286
- 1287
- 1288
- 1289
- 1290
- 1291
- 1292
- 1293
- 1294
- 1295
- 1296
- 1297
- 1298
- 1299
- 1300
- 1301
- 1302
- 1303
- 1304
- Descriptions come with context, i.e. a given description comprises information needed to adequately support the context. For example, a list of items can define a version of a service, but for many contexts an indicated version number is sufficient without the detailed list. The current model focuses on the description needed by a service consumer to understand what the service does, under what conditions the service will do it, how well the service does it, and what steps are needed by the consumer to initiate and complete a service interaction. Such information also enables the service provider to clearly specify what is being provided and the intended conditions of use.
  - Descriptions change over time as, for example, the ingredients and nutrition information for food labeling continues to evolve. A need for transparency of transactions may require additional description for those associated contexts.
  - Description always proceeds from a basis of what is considered 'common knowledge'. This may be social conventions that are commonly expected or possibly codified in law. It is impossible to describe everything and it can be expected that a mechanism as far reaching as SOA will also connect entities where there is inconsistent 'common' knowledge.
  - Descriptions become the collection point of information related to a service or any other resource, but it is not necessarily the originating point or the motivation for generating this information. In particular, given a SOA service as the access to an underlying capability, the service may point to some of the capability's previously generated description, e.g. a service providing access to a data store may also have access to information indicating the freshness of the data.

1305 These points emphasize that there is no one 'right' description for all contexts and for all time. Several  
1306 descriptions for the same subject may exist at the same time, and this emphasizes the importance of the  
1307 description referencing source material maintained by that material's owner rather than having multiple  
1308 copies that become out of synch and inconsistent.

1309 It may also prove useful for a description assembled for one context to cross-reference description  
1310 assembled for another context as a way of referencing ancillary information without overburdening any  
1311 single description. Rather than a single artifact, description can be thought of as a web of documents that  
1312 enhance the total available description.

1313 This Reference Architecture Foundation uses the term service description for consistency with the  
1314 concept defined in the Reference Model. Some SOA literature treats the idea of a 'service contract' as  
1315 equivalent to service description. In the SOA-RAF, the term service description is preferred. Replacing the  
1316 term 'service description' with the term 'service contract' implies that just one side of the interaction is  
1317 governing and misses the point that a single set of policies identified by a service description may lead to  
1318 numerous contracts, i.e. service level agreements, leveraging the same description.

## 1319 **4.1.1 The Model for Service Description**

1320 *Figure 14* shows Service Description as a subclass of the general Description class. As well as *describing*  
1321 a Resource (as we saw in Section 3.2.4.1), a Description is also a subclass of the Resource class. In  
1322 addition, each resource is assumed to *have* a description<sup>5</sup>. The following section discusses the  
1323 relationships among elements of general description and the subsequent sections focus on service  
1324 description. Other descriptions, such as those of participants, are important to SOA but are not  
1325 individually elaborated in this document.

---

<sup>5</sup> The description itself can have further descriptive data such as its version or last revision. The model emphasizes this point but should not be interpreted too rigorously as allowing endless recursion.

1326 **4.1.1.1 Elements Common to General Description**

1327 The general Description class is composed of a number of elements that are expected to be common  
 1328 among all descriptions supporting a service oriented architecture. A registry/repository often contains a  
 1329 subset of the description instance, where the chosen subset is identified as that which facilitates  
 1330 discovery. Additional information contained in a more complete description may be needed to initiate and  
 1331 continue interaction.

1332

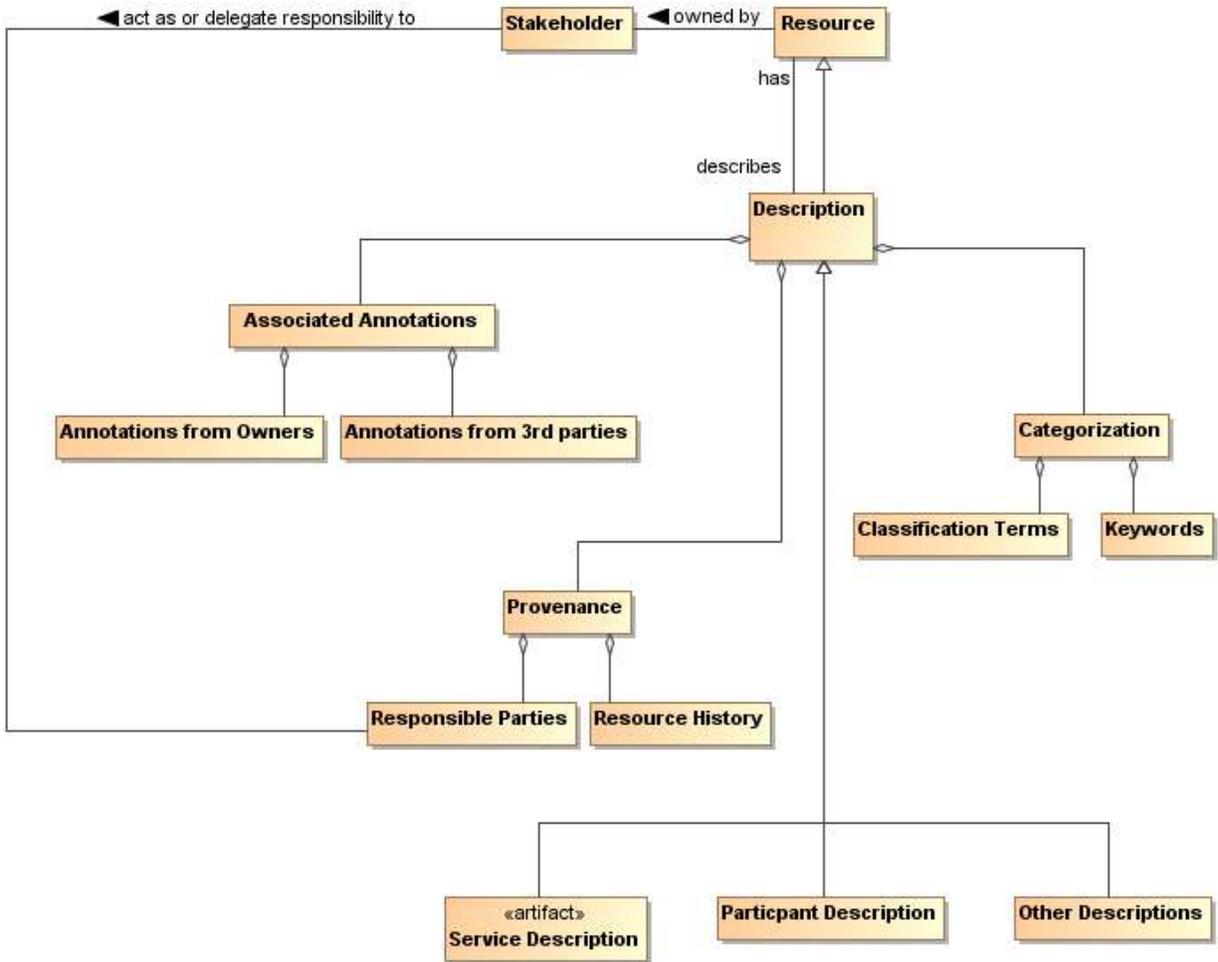

Figure 14 - General Description

1333  
1334

1335 **4.1.1.1.1 Provenance**

1336 While the resource Identifier provides the means to know which subject and subject description are being  
 1337 considered, Provenance as related to the Description class provides information that reflects on the  
 1338 quality or usability of the subject. Provenance specifically identifies the stakeholder (human, defined role,  
 1339 organization, etc.) who assumes responsibility for the resource being described and tracks historic  
 1340 information that establishes a context for understanding what the resource provides and how it has  
 1341 changed over time. Responsibilities may be directly assumed by the stakeholder who owns a resource  
 1342 (see Section 3.2.4.2) or the Owner may designate Responsible Parties for the various aspects of  
 1343 maintaining the resource and provisioning it for use by others. There may be more than one stakeholder  
 1344 identified under Responsible Parties; for example, one stakeholder may be responsible for code  
 1345 maintenance while another is responsible for provisioning of the executable code.

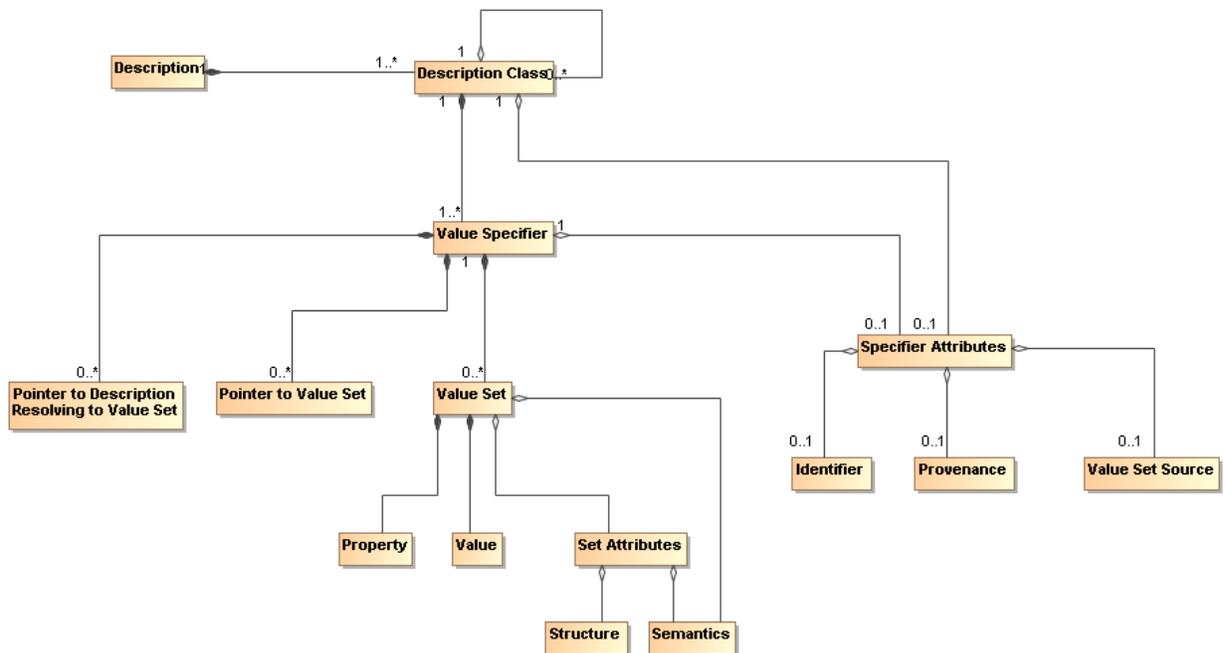

1346 **4.1.1.1.2 Keywords and Classification Terms**

1347 A traditional element of description has been to associate the resource being described with predefined  
1348 keywords or classification taxonomies that derive from referenceable formal definitions and vocabularies.  
1349 This Reference Architecture Foundation does not prescribe which vocabularies or taxonomies may be  
1350 referenced, nor does it limit the number of keywords or classifications that may be associated with the  
1351 resource. It does, however, state that a normative definition of any terms or keywords SHOULD be  
1352 referenced, whether that be a representation in a formal ontology language, a pointer to an online  
1353 dictionary, or any other accessible source. See Section 4.1.1.2 for further discussion on associating  
1354 semantics with assigned values.

1355 **4.1.1.1.3 Associated Annotations**

1356 The general description instance may also reference associated documentation that is in addition to that  
1357 considered necessary in this model. For example, the owner of a service may have documentation on  
1358 best practices for using the service. Alternately, a third party may certify a service based on their own  
1359 criteria and certification process; this may be vital information to other prospective consumers if they were  
1360 willing to accept the certification in lieu of having to perform another certification themselves. Note, while  
1361 the examples of Associated Documentation presented here are related to services, the concept applies  
1362 equally to description of other entities.

1363 **4.1.1.2 Assigning Values to Description Instances**

1364  
1365 *Figure 15 - Representation of a Description*

1366 *Figure 14* shows the template for a general description, but individual description instances depend on the  
1367 ability to associate meaningful values with the identified elements. *Figure 15* shows a model for a  
1368 collection of information that provides for value assignment and traceability for both the meaning and the  
1369 source of a value. The model is not meant to replace existing or future schema or other structures that  
1370 have or will be defined for specific implementations, but it is meant as guidance for the information such  
1371 structures need to capture to generate sufficient description. It is expected that tools will be developed to  
1372 assist the user in populating description and auto-filling many of these fields, and in that context, this  
1373 model provides guidance to the tool developers.

1374 In *Figure 15*, each class has an associated value specifier or is made up of components that eventually  
1375 resolve to a value specifier. For example, Description has several components, one of which is  
1376 Categorization, which would have an associated value specifier.

1377 A value specifier consists of

1378     • a collection of value sets with associated property-value pairs, pointers to such value sets, or

1379     pointers to descriptions that eventually resolve to value sets that describe the component; and

1380     • attributes that qualify the value specifier and the value sets it contains.

1381 The qualifying attributes for the value specifier include

1382     • an optional identifier that would allow the value set to be defined, accessed, and reused

1383     elsewhere;

1384     • provenance information that identifies the person (individual or organization) who has

1385     responsibility for assigning the value sets to any description component;

1386     • an optional source of the value set, if appropriate and meaningful, e.g. if a particular data source

1387     is mandated.

1388 If the value specifier is contained within a higher-level component (such as Service Description containing

1389 Service Functionality), the component may assume values from the attributes of its container.

1390 Note, provenance as a qualifying attribute of a value specifier is different from provenance as part of an

1391 instance of Description. Provenance for a service identifies those who own and are responsible for the

1392 service, as described in Section 3.2.4. Provenance for a value specifier identifies who is responsible for

1393 choosing and assigning values to the value sets that comprise the value specifier. It is assumed that

1394 granularity at the value specifier level is sufficient and provenance is not required for each value set.

1395 The value set also has attributes that define its structure and semantics.

1396     • The semantics of the value set property should be associated with a semantic context conveying

1397     the meaning of the property within the execution context, where the semantic context could vary

1398     from a free text definition to a formal ontology.

1399     • For numeric values, the structure would provide the numeric format of the value and the

1400     ‘semantics’ would be conveyed by a dimensional unit with an identifier to an authoritative source

1401     defining the dimensional unit and preferred mechanisms for its conversion to other dimensional

1402     units of like type.

1403     • For nonnumeric values, the structure would provide the data structure for the value

1404     representation and the semantics would be an associated semantic model.

1405     • For pointers, architectural guidelines would define the preferred addressing scheme.

1406 The value specifier may indicate a default semantic model for its component value sets and the individual

1407 value sets may provide an override.

1408 The property-value pair construct is introduced for the value set to emphasize the need to identify

1409 unambiguously both what is being specified and what is a consistent associated value. The further

1410 qualifying of Structure and Semantics in the Set Attributes allows for flexibility in defining the form of the

1411 associated values.

1412 **4.1.1.3 Model Elements Specific to Service Description**

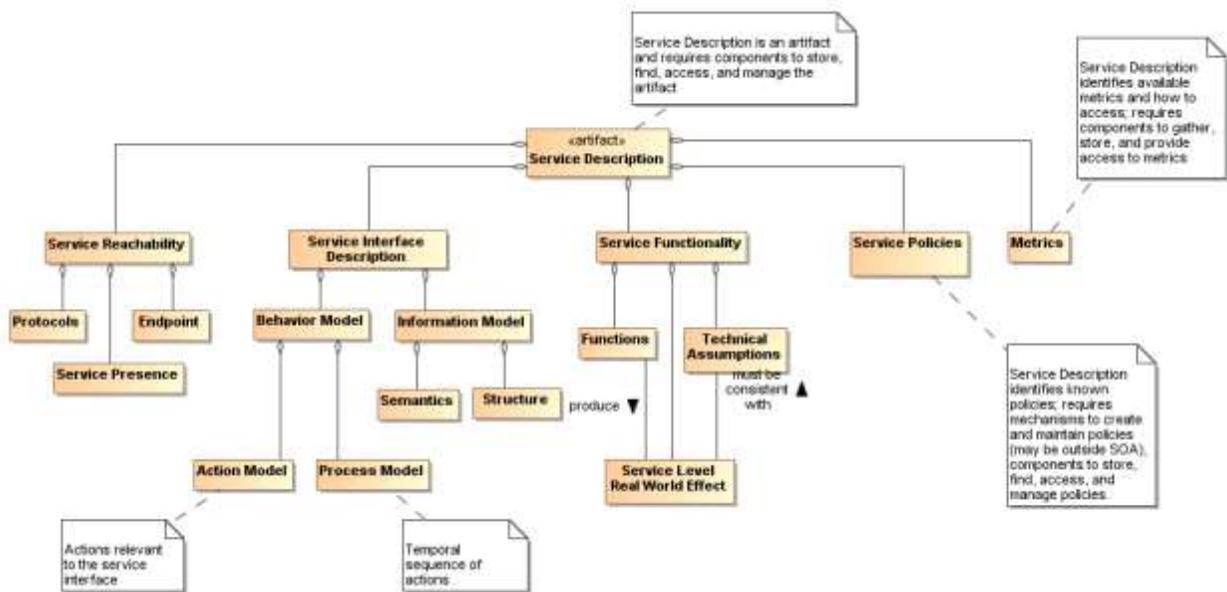

Figure 16 - Service Description

1413  
1414

1415 The major elements for the Service Description subclass follow directly from the areas discussed in the  
1416 Reference Model. Here, we discuss the detail shown in *Figure 16* and the purpose served by each  
1417 element of service description. For example, Service Policies as included in *Figure 16* indicate those  
1418 policies that affect conditions of use of the service; however, while the description may link to detailed  
1419 policy documents, it is not the purpose of description to justify or elaborate on the rationale for the  
1420 policies. Similarly, Service Interface Description as included in *Figure 16* captures information about what  
1421 interactions are supported by the service via its Behavior Model and the information exchange needed to  
1422 carry out those interactions in accordance with the service's Information Model; it is not the coded  
1423 interface.

1424 Note, the intent in the subsections that follow is to describe how a particular element, such as the service  
1425 interface description, is reflected in the service description, not to elaborate on the details of that element.

1426 **4.1.1.3.1 Service Interface Description**

1427 As noted in the Reference Model, the service interface is the means for interacting with a service. For the  
1428 SOA-RAF and as shown in Section 4.3 the service interface supports an exchange of messages, where

- 1429 • the message conforms to a referenceable message exchange pattern (MEP, covered below in  
1430 Section 4.3.3.1),
- 1431 • the message payload conforms to the structure and semantics of the indicated information model,
- 1432 • the messages are used to denote events related to or actions against the service, where the  
1433 actions are specified in the action model and any required sequencing of actions is specified in  
1434 the process model.

1435 The Service Interface Description element as shown in *Figure 17* includes the information needed to carry  
1436 out this message exchange in order to realize the service behavior described. In addition to the  
1437 Information Model that conveys the Semantics and Structure of the message, the Service Interface  
1438 Description indicates what behavior can be expected through interactions conveyed in the Action and  
1439 Process Models.

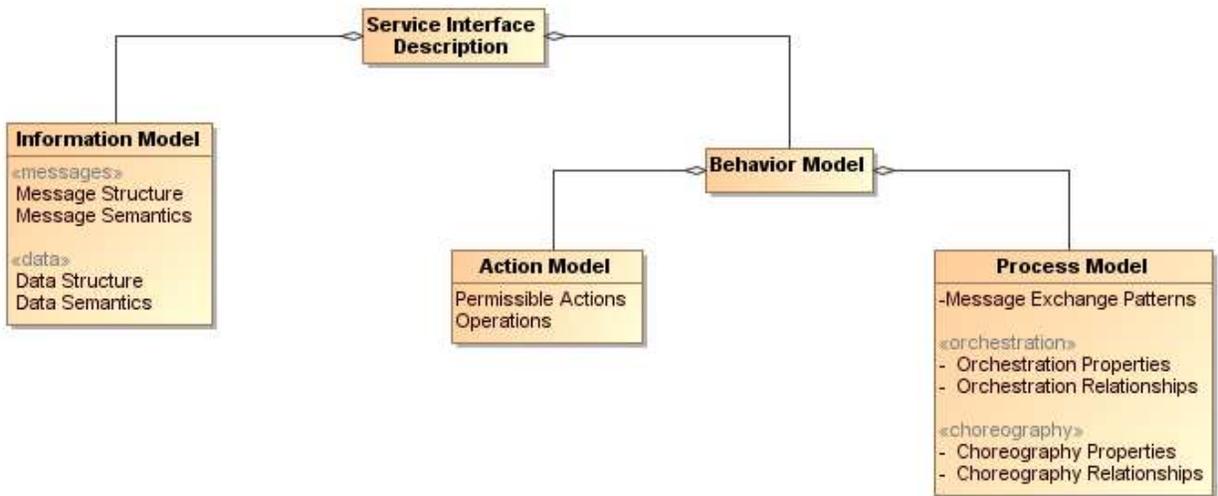

Figure 17 - Service Interface Description

1440  
1441

1442 Note we distinguish the structure and semantics of the message from that of the underlying **protocol** that  
1443 conveys the message. The message structure may include nested structures that are independently  
1444 defined, such as an enclosing envelope structure and an enclosed data structure.

1445 These aspects of messages are discussed in more detail in Section 4.3.2.

#### 1446 4.1.1.3.2 Service Reachability

1447 Service reachability, as modeled in Section 4.2.2.3 enables service participants to locate and interact with  
1448 one another. To support service reachability, the service description should indicate the **endpoints** (also  
1449 modeled and defined in that section) to which a service consumer can direct messages to invoke actions  
1450 and the protocol to be used for message exchange using that endpoint.

1451 As generally applied to an action, the endpoint is the conceptual location where one applies an action;  
1452 with respect to service description, it is the actual address where a message is sent.

#### 1453 4.1.1.3.3 Service Functionality

1454 While the service interface and service reachability are concerned with the mechanics of using a service,  
1455 service functionality and performance metrics (discussed in Section 4.1.1.3.4) describe what can be  
1456 expected as a result of interacting with a service. Service Functionality, shown in *Figure 16* as part of the  
1457 overall Service Description model and extended in *Figure 18*, is a clear expression of service function(s)  
1458 and the real world effects of invoking the function. The Functions represent business activities in some  
1459 domain that produce the desired real world effects.

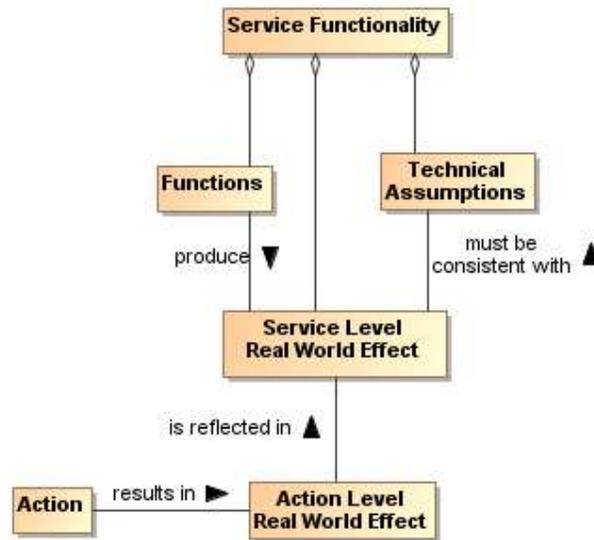

Figure 18 - Service Functionality

1460  
1461

1462 The Service Functionality may also be limited by technical assumptions/constraints that underlie the  
1463 effects that can result. Technical constraints are defined as domain specific restrictions and may express  
1464 underlying physical limitations, such as flow speeds must be below sonic velocity or disk access that  
1465 cannot be faster than the maximum for its host drive. Technical constraints are related to the underlying  
1466 capability accessed by the service. In any case, the real world effects must be consistent with the  
1467 technical assumptions/constraints.

1468 In *Figure 16* and *Figure 18*, we specifically refer to the descriptions of **Service Level** and **Action Level**  
1469 **Real World Effects**.

#### 1470 **Service Level Real World Effect**

1471 A specific change in the **state** or the information returned as a result of interacting with a service.

#### 1472 **Action Level Real World Effect**

1473 A specific change in the **state** or the information returned as a result of interacting through a  
1474 specific action.

1475 Service description describes the service as a whole while the component aspects should contribute to  
1476 that whole. Thus, while individual Actions may contribute to the real world effects to be realized from  
1477 interaction with the service, there would be a serious disconnect for Actions to contribute real world  
1478 effects that could not consistently be reflected in the Service Level Real World Effects and thus the  
1479 Service Functionality. The relationship to Action Level Real World Effects and the implications on defining  
1480 the scope of a service are discussed in Section 4.1.2.1.

1481 Elements of Service Functionality may be expressed as natural language text, reference an existing  
1482 taxonomy of functions or other formal model.

#### 1483 **4.1.1.3.4 Service Policies, Metrics, and Compliance Records**

1484 Policies prescribe the conditions and constraints for interacting with a service and impact the willingness  
1485 to continue visibility with the other participants. Whereas technical constraints are statements of 'physical'  
1486 fact, policies are subjective assertions made by the service provider (sometimes as passed on from  
1487 higher authorities).

1488 The service description provides a central location for identifying what policies have been asserted by the  
1489 service provider. The specific representation of the policy, e.g. in some formal policy language, is outside  
1490 of the service description. The service description would reference the normative definition of the policy.

1491 Policies may also be asserted by other participants, as illustrated by the model shown in *Figure 19*.  
1492 Policies that are generally applicable to any interaction with the service are asserted by the service  
1493 provider and included in the Service Policies section of the service description.

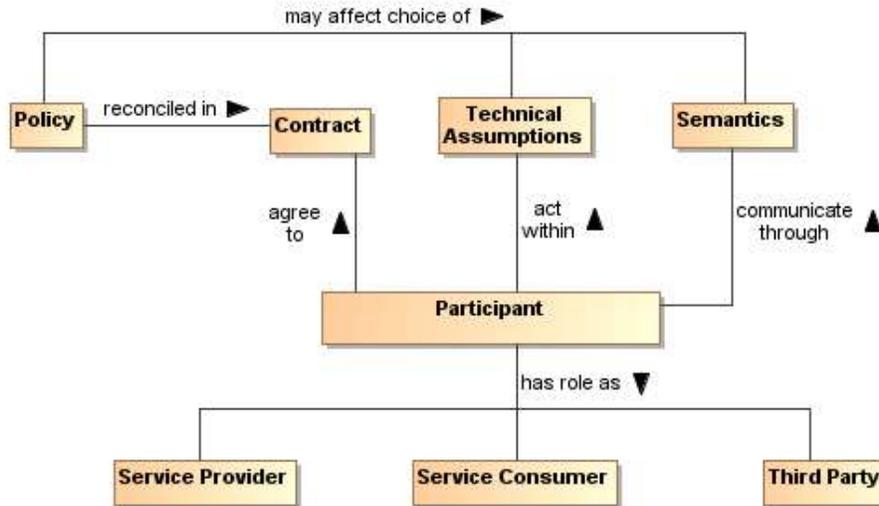

Figure 19 - Model for Policies and Contracts as related to Service Participants

1494  
1495

1496 In *Figure 19*, we specifically refer to policies at the service level. In a similar manner to that discussed for  
 1497 Service Level vs. Action Level Real World Effects in Section 4.1.1.3.3, individual Actions may have  
 1498 associated policies stating conditions for performing the action, but these must be reflected in and be  
 1499 consistent with the policies made visible at the service level and thus the description of the service as a  
 1500 whole. The relationship to Action Level Policies and the implications on defining the scope of a service  
 1501 are discussed in Section 4.1.2.1.

1502 As noted in *Figure 19*, the policies asserted may be reflected as Technical Assumptions/Constraints that  
 1503 available services or their underlying capabilities must be capable of meeting; it may similarly affect the  
 1504 semantics that can be used. For example of the former, there may be a policy that specifies the surge  
 1505 capacity to be accommodated by a server, but a service that is not designed to make use of the larger  
 1506 server capacity would not satisfy the intent of the policy and would not be appropriate to use. For the  
 1507 latter, a policy may require that only services that support interaction via a community-sponsored  
 1508 vocabulary can be used.

1509 Contracts are agreements among the participants. The contract may reconcile inconsistent policies  
 1510 asserted by the participants or may specify details of the interaction. Service level agreements (SLAs) are  
 1511 one of the commonly used categories of contracts.

1512 The definition and later enforcement of policies and contracts are predicated on the potential for  
 1513 measurement; the relationships among the relevant concepts are shown in the model in *Figure 20*.  
 1514 Performance Metrics identify quantities that characterize the speed and quality of realizing the real world  
 1515 effects produced using the SOA service; in addition, policies and contracts may depend on  
 1516 nonperformance metrics, such as whether a license is in place to use the service. Some of these metrics  
 1517 may reflect the underlying capability, some metrics may reflect processing of the SOA service, and some  
 1518 metrics may include expected network overhead. The metrics should be carefully defined to avoid  
 1519 confusion in exactly what is being reported, for example, a case where the service processing time is  
 1520 reported as if it were the total time including the capability and network processing but is only measuring  
 1521 the service processing.

1522

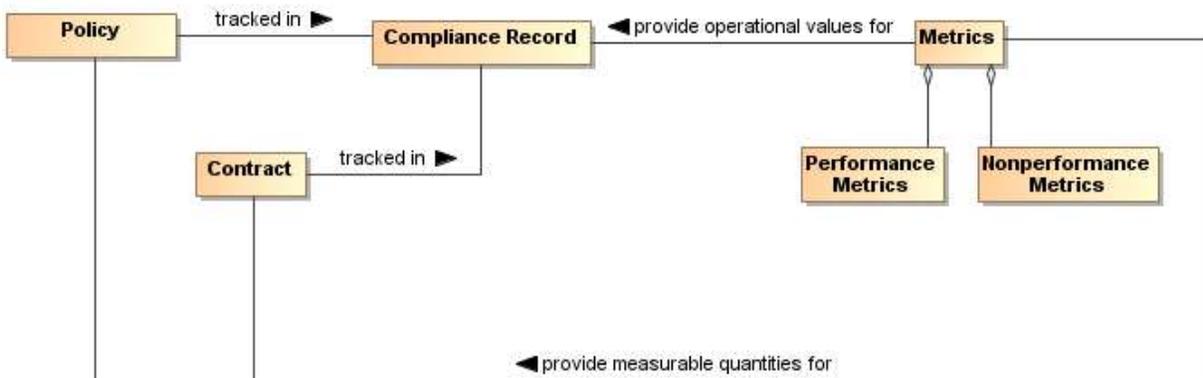

Figure 20 - Policies and Contracts, Metrics, and Compliance Records

1523  
1524

1525 As with many quantities, the metrics associated with a service are not themselves defined by this Service  
1526 Description Model because it is not known *a priori* which metrics are being collected or otherwise checked  
1527 by the services, the SOA infrastructure, or other resources that participate in the SOA interactions.  
1528 However, the service description SHOULD provide a placeholder (possibly through a link to an externally  
1529 compiled list) for identifying which metrics are available and how these can be accessed.

1530 The use of metrics to evaluate compliance and the results of compliance evaluation SHOULD be  
1531 maintained in compliance records and the means to access the compliance records MAY be included in  
1532 the Service Policies portion of the service description. For example, the description may be in the form of  
1533 static information (e.g. over the first year of operation, this service had a 91% availability), a link to a  
1534 dynamically generated metric (e.g. over the past 30 days, the service has had a 93.3% availability), or  
1535 access to a dynamic means to check the service for current availability (e.g., a ping). The relationship  
1536 between service **presence** and the presence of the individual actions that can be invoked is discussed  
1537 under Reachability in Section 4.2.2.3.

1538 Note, even when policies relate to the perspective of a single participant, policy compliance can be  
1539 measured and policies may be enforceable without contractual agreement with other participants. While  
1540 certain elements of contracts and contract compliance are likely private, public aspects of compliance  
1541 should be reflected in the compliance record information referenced in the service description. This  
1542 provides input to evidence that supports determining willingness as described in Section 3.2.5.1.

## 1543 4.1.2 Use of Service Description

### 1544 4.1.2.1 Service Description in support of Service Interaction

1545 If we assume we have awareness, the service participants must still establish willingness and presence to  
1546 ensure full visibility (See Section 4.2) and to interact with the service. Service description provides  
1547 necessary information for many aspects of preparing for and carrying through with interaction. Recall the  
1548 fundamental definition of a SOA service as a mechanism to access an underlying capability; the service  
1549 description describes this mechanism and its use. It lays the groundwork for what can occur, whereas  
1550 service interaction comprises the specifics through which real-world effects are realized.

1575 scheduled maintenance and access attempts at these times would fail. Dependencies related to the  
1576 process model do not affect the presence of a service although these may affect whether the business  
1577 function successfully completes. The service as a whole may provide fallback if a dependency is not met,  
1578 and the service description may indicate functionality without explicitly containing details of how  
1579 dependencies are satisfied or otherwise mitigated.

1580 The conditions under which an action can be invoked may depend on policies associated with the action.  
1581 The Action Level Policies must be reflected in (or subsumed by) the Service Policies because such  
1582 policies may be critical to determining whether the conditions for use of the service are consistent with the  
1583 policies asserted by the service consumer. For example, if an action requires interaction with another  
1584 service and that other service has licensing requirements, then the service with such an action also has  
1585 the same requirement. The Service Policies are included in the service description.

1586 Similarly, the result of invoking an action is one or more real world effects, and any Action Level Real  
1587 World Effects must be reflected in the Service Level Real World Effect included in the service description.  
1588 The unambiguous expression of action level policies and real world effects as service counterparts is  
1589 necessary to adequately describe what constitutes the service interaction. For example, if an action  
1590 allows for the tracking of user preferences, then the service with such an action results in the same real  
1591 world effect.

1592 An adequate service description must provide a consumer with information needed to determine if the  
1593 service policies, the (business) functions, and service-level real world effects are of interest, and there is  
1594 nothing in the technical constraints that preclude use of the service.

1595 Note at the service level, the business functions are not concerned with the action or process models.  
1596 These models are detailed separately.

1597 The service description is not intended to be isolated documentation but rather an integral part of service  
1598 use. Changes in service description should immediately be made known to consumers and potential  
1599 consumers.

#### 1600 **4.1.2.2 Description and Invoking Actions Against a Service**

1601 At this point, let us assume the descriptions were sufficient to establish willingness; see Section 4.2.2.2.  
1602 *Figure 21* indicates the service endpoint establishes where to actually carry out the interaction. This is  
1603 where we start considering the action and process models.

1604 The action model identifies the multiple actions a user can perform against a service and the user would  
1605 perform these in the context of the process model as specified or referenced under the Service Interface  
1606 Description portion of Service Description. For a given business function, there is a corresponding  
1607 process model, where any process model may involve multiple actions. From the above discussion of  
1608 model elements of description we may conclude (1) actions have reachability information, including  
1609 endpoint and presence, (2) presence of service is some aggregation of presence of its actions, (3) action  
1610 preconditions and service dependencies do not affect presence although these may affect successful  
1611 completion.

1612 Having established visibility, the interaction can proceed. Given a business function, the consumer knows  
1613 what will be accomplished (the service functionality), the conditions under which interaction will proceed  
1614 (service policies), and the process that must be followed (the process model). The remaining question is  
1615 how the description information for structure and semantics enable interaction.

1616 We have established the importance of the process model in identifying relevant actions and their  
1617 sequence. Interaction proceeds through messages and thus it is the syntax and semantics of the  
1618 messages with which we are here concerned. A common approach is to define the structure and  
1619 semantics that can appear as part of a message; then assemble the pieces into messages; and,  
1620 associate messages with actions. Actions make use of structure and semantics as defined in the  
1621 information model to describe its legal messages.

1622 The process model identifies actions to be performed against a service and the sequence for performing  
1623 the actions. For a given action, the Reachability portion of description indicates the protocol bindings that  
1624 are available, the endpoint corresponding to a binding, and whether there is presence at that endpoint. An  
1625 interaction is through the exchange of messages that conform to the structure and semantics defined in  
1626 the information model and the message sequence conforming to the action's identified MEP. The result is

1627 some portion of the real world effect that must be assessed and/or processed (e.g. if an error exists, that  
1628 part that covers the error processing would be invoked).

#### 1629 **4.1.2.3 The Question of Multiple Business Functions**

1630 Action level effects and policies must be reflected at the service level for service description to support  
1631 visibility.

1632 It is assumed that a SOA service represents an identifiable business function to which policies can be  
1633 applied and from which desired business effects can be obtained. While contemporary discussions of  
1634 SOA services and supporting standards do not constrain what actions or combinations of actions can or  
1635 should be defined for a service, the SOA-RAF considers the implications of service description in defining  
1636 the range of actions appropriate for an individual SOA service.

1637 Consider the situation if a given SOA service is the mechanism for access to multiple independent (but  
1638 loosely related) business functions. These are not multiple effects from a single function but multiple  
1639 functions with potentially different sets of effects for each function. A service can have multiple actions a  
1640 user may perform against it, and this does not change with multiple business functions. As an individual  
1641 business function corresponds to a process model, so multiple business functions imply multiple process  
1642 models. The same action may be used in multiple process models but the aggregated service presence  
1643 would be specific to each business function because the components being aggregated may be different  
1644 between process models. In summary, for a service with multiple business functions, each function has  
1645 (1) its own process model and dependencies, (2) its own aggregated presence, and (3) possibly its own  
1646 list of policies and real world effects.

1647 A common variation on this theme is for a single service to have multiple endpoints for different levels of  
1648 quality of service (QoS), e.g. Gold, Silver, and Bronze. Different QoS imply separate statements of policy,  
1649 separate endpoints, possibly separate dependencies, and so on. One could say the QoS variation does  
1650 not require this because there can be a single QoS policy that encompasses the variations, and all other  
1651 aspects of the service would be the same except for the endpoint used for each QoS. However, the  
1652 different aspects of policy at the service level would need to be mapped to endpoints, and this introduces  
1653 an undesirable level of coupling across the elements of description. In addition, it is obvious that  
1654 description at the service level can become very complicated if the number of combinations is allowed to  
1655 grow.

1656 One could imagine a service description that is basically a container for action descriptions, where each  
1657 action description is self-contained; however, this would lead to duplication of description components  
1658 across actions. If common description components are factored, this either is limited to components  
1659 common across all actions or requires complicated tagging to capture the components that often but do  
1660 not universally apply.

1661 If a provider cannot describe a service as a whole but must describe every action, this leads to the  
1662 situation where it may be extremely difficult to construct a clear and concise service description that can  
1663 effectively support discovery and use without tedious logic to process the description and assemble the  
1664 available permutations. In effect, if adequate description of an action begins to look like description of a  
1665 service, it may be best to have it as a separate service.

1666 Recall, more than one service can access the same underlying capability, and this is appropriate if a  
1667 different real world effect is to be exposed. Along these lines, one can argue that different QoS are  
1668 different services because getting a response in one minute rather than one hour is more than a QoS  
1669 difference; it is a fundamental difference in the business function being provided.

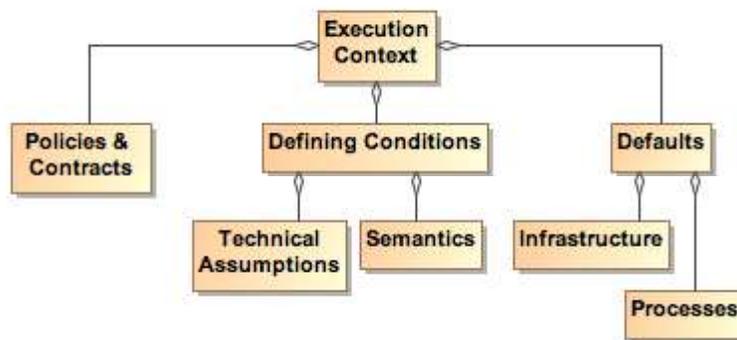

1670 As a best practice, the criterion for whether a service is appropriately scoped may be the ease or difficulty  
1671 in creating an unambiguous service description. A consequence of having tightly-scoped services is there  
1672 will likely be a greater reliance on combining services, i.e. more fundamental business functions, to create  
1673 more advanced business functions. This is consistent with the principles of service oriented architecture  
1674 and is the basic position of this Reference Architecture Foundation, although not an absolute  
1675 requirement. Combining services increases the reliance on understanding and implementing the concepts  
1676 of orchestration, choreography, and other approaches yet to be developed; these are discussed in more  
1677 detail in section 4.4 Interacting with Services.

1678 **4.1.2.4 Service Description, Execution Context, and Service Interaction**

1679 The service description must provide sufficient information to support service visibility, including the  
1680 willingness of service participants to interact. However, the corresponding descriptions for providers and  
1681 consumers may both contain policies, technical assumptions, constraints on semantics, and other  
1682 technical and procedural conditions that must be aligned to define the terms of willingness. The  
1683 agreements that encapsulate the necessary alignment form the basis upon which interactions may  
1684 proceed – in the Reference Model, this collection of agreements and the necessary environmental  
1685 support establish the execution context.

1686 To illustrate execution context of a service interaction, consider a Web-based system for timecard entry.  
1687 For an employee onsite at an employer facility, the execution context requires a computer connected to  
1688 the local network and the employee must enter their network ID and password. Relevant policies include  
1689 that the employee must maintain the most recent anti-virus software and virus definitions for any  
1690 computer connected to the network.

1691 For the same employee connecting from offsite, the execution context specifies the need for a computer  
1692 with installed VPN software and a security token to negotiate the VPN connection. The execution context  
1693 also includes proxy settings as needed to connect to the offsite network. The employee must still comply  
1694 with the requirements for onsite computers and access, but the offsite execution context includes  
1695 additional items before the employee can access the same underlying capability and realize the same  
1696 real world effects, i.e. the timecard entries.

1697  
1698

Figure 22 - Execution Context

1699 *Figure 22* shows a few broad categories found in execution context. These are not meant to be  
1700 comprehensive. Other items may need to be included to provide a sufficient description of the interaction  
1701 conditions. Any other items not explicitly noted in the model but needed to set the environment SHOULD  
1702 be included in the execution context.

1703 While the execution context captures the conditions under which interaction can occur, it does not capture  
1704 the specific service invocations that do occur in a specific interaction. A service interaction as modeled in  
1705 *Figure 23* introduces the concept of an Interaction Description that is composed of both the Execution  
1706 Context and an Interaction Log. The execution context specifies the set of conditions under which the  
1707 interaction occurs and the interaction log captures the sequence of service interactions that occur within  
1708 the execution context. This sequence should follow the Process Model but can include details beyond  
1709 those specified there. For example, the Process Model may specify an action that results in identifying a  
1710 data source, and the identified source is used in a subsequent action. The Interaction Log would record  
1711 the specific data source used.

1712 The execution context can be thought of as a container in which the interaction occurs and the interaction  
1713 log captures what happens inside the container. This combination is needed to support auditability and  
1714 repeatability of the interactions.

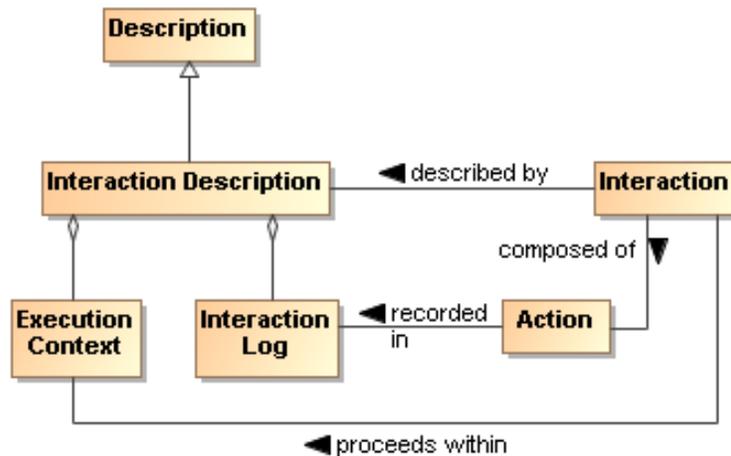

Figure 23 - Interaction Description

1715  
1716

1717 SOA allows flexibility to accomplish both repeatability and reusability. In facilitating reusability, a service  
1718 can be updated without disrupting the user experience of the service. So, Google can improve their  
1719 ranking algorithm without notifying the user about the details of the update.

1720 However, it may also be vital for the consumer to be able to recreate past results or to generate  
1721 consistent results in the future, and information such as what conditions, which services, and which  
1722 versions of those services were used is indispensable in retracing one's path. The interaction log is a  
1723 critical part of the resulting real world effects because it defines how the effects were generated and  
1724 possibly the meaning of observed effects. This increases in importance as dynamic composability  
1725 becomes more feasible. In essence, a result has limited value if one does not know how it was generated.

1726 The interaction log SHOULD be a detailed trace for a specific interaction, and its reuse is limited to  
1727 duplicating that interaction. An execution context can act as a template for identical or similar interactions.  
1728 Any given execution context MAY define the conditions of future interactions.

1729 Such uses of execution context imply (1) a standardized format for capturing execution context and (2) a  
1730 subclass of general description could be defined to support visibility of saved execution contexts. The  
1731 specifics of the relevant formats and descriptions are beyond the scope of this document.

1732 A service description is unlikely to track interaction descriptions or the constituent execution contexts or  
1733 interaction logs that include mention of the service. However, as appropriate, linking to specific instances  
1734 of either of these could be done through associated annotations.

### 1735 4.1.3 Relationship to Other Description Models

1736 While the representation shown in Figure 15 is derived from considerations related to service description, it  
1737 is acknowledged that other metadata standards are relevant and should, as possible, be incorporated into  
1738 this work. Two standards of particular relevance are the Dublin Core Metadata Initiative (DCMI) [DCMI]  
1739 and ISO 11179 [ISO 11179], especially Part 5.

1740 When the service description (or even the general description class) is considered as the DCMI  
1741 'resource', Figure 15 aligns nicely with the DCMI resource model. While some differences exist, these are  
1742 mostly in areas where DCMI goes into detail that is considered beyond the scope of the current  
1743 Reference Architecture Foundation. For example, DCMI defines classes of 'shared semantics' whereas  
1744 this Reference Architecture Foundation considers that an identification of relevant semantic models is  
1745 sufficient. Likewise, the DCMI Description Model goes into the details of possible syntax encodings  
1746 whereas for the Reference Architecture Framework it is sufficient to identify the relevant formats.

1747 With respect to ISO 11179 Part 5, the metadata fields defined in that reference may be used without  
1748 prejudice as the properties in Figure 15. Additionally, other defined metadata sets may be used by the  
1749 service provider if the other sets are considered more appropriate, i.e. it is fundamental to this reference  
1750 architecture to identify the need and the means to make vocabulary declarations explicit but it is beyond  
1751 the scope to specify which vocabularies are to be used. In addition, the identification of domain of the

1752 properties and range of the values has not been included in the current Reference Architecture  
1753 discussion, but the text of ISO 11179 Part 5 can be used consistently with the model prescribed in this  
1754 document.

1755 Description as defined here considers a wide range of applicability and support of the principles of service  
1756 oriented architecture. Other metadata models can be used in concert with the model presented here  
1757 because most of these focus on a finer level of detail that is outside the present scope, and so provide a  
1758 level of implementation guidance that can be applied as appropriate.

#### 1759 4.1.4 Architectural Implications

1760 The definition of service description has numerous architectural implications for the SOA ecosystem:

- 1761 • The real world effects that the service description definition support must be consistent with the  
1762 technical assumptions/constraints. In particular, any Action Level Real World Effect **MUST** be  
1763 reflected in the Service Level Real World Effect included in the sedcription.
- 1764 • The service description definition changes over time and its contents will reflect changing  
1765 requirements and context. The service description definition **MUST** therefore have:
  - 1766 ○ mechanisms to support the storage, referencing, and access to normative definitions of  
1767 one or more versioning schemes that may be applied to identify different aggregations of  
1768 descriptive information, where the different schemes may be versions of a versioning  
1769 scheme itself;
  - 1770 ○ configuration management mechanisms to capture the contents of each aggregation and  
1771 apply a unique identifier in a manner consistent with an identified versioning scheme;
  - 1772 ○ one or more mechanisms to support the storage, referencing, and access to conversion  
1773 relationships between versioning schemes, and the mechanisms to carry out such  
1774 conversions.
- 1775 • Description makes use of defined semantics, where the semantics **MAY** be used for  
1776 categorization or providing other property and value information for description classes. In such  
1777 cases, the service description **MUST** have:
  - 1778 ○ semantic models that provide normative descriptions of the utilized terms, where the  
1779 models may range from a simple dictionary of terms to an ontology showing complex  
1780 relationships and capable of supporting enhanced reasoning;
  - 1781 ○ mechanisms to support the storage, referencing, and access to these semantic models;
  - 1782 ○ configuration management mechanisms to capture the normative description of each  
1783 semantic model and to apply a unique identifier in a manner consistent with an identified  
1784 versioning scheme;
  - 1785 ○ one or more mechanisms to support the storage, referencing, and access to conversion  
1786 relationships between semantic models, and the mechanisms to carry out such  
1787 conversions.
- 1788 • Once awareness exists, the service participants **MUST** still establish willingness and presence to  
1789 ensure full visibility (See Section 4.2).
- 1790 • The Service Description **MUST** provide a consumer with information needed to: determine the  
1791 service functionality; the conditions under which interaction can proceed (service policies and  
1792 process model); the intended Service Level Real World Effects; any technical constraints that  
1793 might preclude use of the service.
- 1794 • Changes in Service Description **SHOULD** be made available immediately to actual and potential  
1795 consumers.
- 1796 • Actions **MAY** have associated policies stating conditions for performing the action, but these  
1797 **MUST** be reflected in and be consistent with the policies made visible at the service level and  
1798 thus the description of the service as a whole.
- 1799 • Policies asserted **MAY** be reflected as Technical Assumptions/Constraints that available services  
1800 or their underlying capabilities **MUST** be capable of meeting.
- 1801 • Descriptions include reference to policies defining conditions of use. In this sense, policies are  
1802 also resources that need to be visible, discoverable, and accessible. The service description (as  
1803 also enumerated under governance) **MUST** have:

- 1804 ○ description of policies, including a unique identifier for the policy and a sufficient,  
1805 preferably machine processable, representation of the meaning of terms used to describe  
1806 the policy, its functions, and its effects;
- 1807 ○ a method to enable searching for policies that best meet the search criteria specified by  
1808 the service participant; where the discovery mechanism has access to the individual  
1809 policy descriptions, possibly through some repository mechanism;
- 1810 ○ accessible storage of policies and policy descriptions, so service participants can access,  
1811 examine, and use the policies as defined.
- 1812 • Descriptions include references to metrics that describe the operational characteristics of the  
1813 subjects being described. The service description definition (as also partially enumerated under  
1814 governance) **MUST** have:
  - 1815 ○ infrastructure monitoring and reporting information on SOA resources;
  - 1816 ○ possible interface requirements to make accessible metrics information generated;
  - 1817 ○ mechanisms to catalog and enable discovery of which metrics are available for a  
1818 described resources and information on how these metrics can be accessed;
  - 1819 ○ mechanisms to catalog and enable discovery of compliance records associated with  
1820 policies and contracts that are based on these metrics.
- 1821 • Descriptions of the interactions are important for enabling auditability and repeatability, thereby  
1822 establishing a context for results and support for understanding observed change in performance  
1823 or results. Thus, the service description definition **MUST** have:
  - 1824 ○ one or more mechanisms to capture, describe, store, discover, and retrieve interaction  
1825 logs, execution contexts, and the combined interaction descriptions;
  - 1826 ○ one or more mechanisms for attaching to any results the means to identify and retrieve  
1827 the interaction description under which the results were generated.
- 1828 • Descriptions may capture very focused information subsets or can be an aggregate of numerous  
1829 component descriptions. Service description is an example of an aggregate for which manual  
1830 maintenance of the whole would not be feasible. Thus, the service description definition **MUST**  
1831 have:
  - 1832 ○ tools to facilitate identifying description elements that are to be aggregated to assemble  
1833 the composite description;
  - 1834 ○ tools to facilitate identifying the sources of information to associate with the description  
1835 elements;
  - 1836 ○ tools to collect the identified description elements and their associated sources into a  
1837 standard, referenceable format that can support general access and understanding;
  - 1838 ○ tools to automatically update the composite description as the component sources  
1839 change, and to consistently apply versioning schemes to identify the new description  
1840 contents and the type and significance of change that occurred.
- 1841 • The description is the source of vital information in establishing willingness to interact with a  
1842 resource, reachability to make interaction possible, and compliance with relevant conditions of  
1843 use. Thus, the service description definition **MUST** have:
  - 1844 ○ one or more discovery mechanisms that enable searching for described resources that  
1845 best meet the criteria specified by a service participant;
  - 1846 ○ tools to appropriately track users of the descriptions and notify them when a new version  
1847 of the description is available.
- 1848 • The service description **MUST** provide sufficient information to support service visibility, including  
1849 the willingness of service participants to interact. However, the corresponding descriptions for  
1850 providers and consumers may both contain policies, technical assumptions, constraints on  
1851 semantics, and other technical and procedural conditions that must be aligned to define the terms  
1852 of willingness

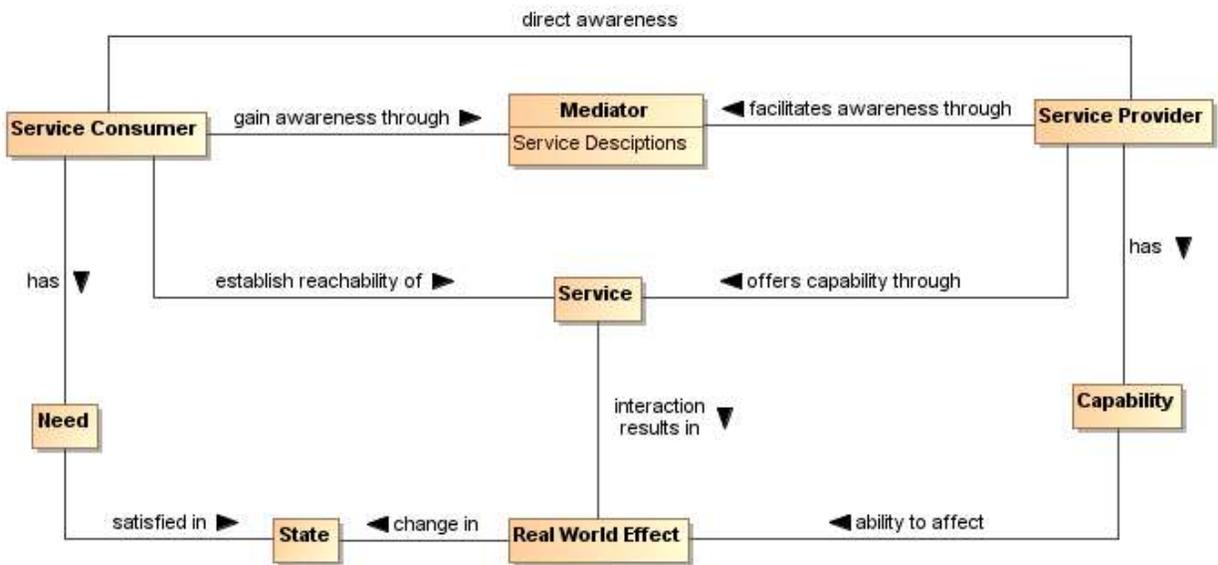

## 1853 4.2 Service Visibility Model

1854 One of the key requirements for participants interacting with each other in the context of a SOA  
1855 ecosystem is achieving visibility: before services can interoperate, the participants have to be visible to  
1856 each other using whatever means are appropriate. The Reference Model analyzes visibility in terms of  
1857 awareness, willingness, and reachability. In this section, we explore how visibility may be achieved.

1858 **4.2.1 Visibility to Business**

1859 The relationship of visibility to the SOA ecosystem encompasses both human social structures and  
 1860 automated IT mechanisms. *Figure 24* depicts a business setting that is a basis for visibility as related to  
 1861 the Social Structure Model (*Figure 3*) in the Participation in a SOA Ecosystem view (see Section 3.1). The  
 1862 participants acting in the various roles of service consumers, mediators, and service providers may have  
 1863 direct awareness or mediated awareness where mediated awareness is achieved through some third  
 1864 party. A consumer's willingness to use a service is reflected by the consumer's presumption of satisfying  
 1865 goals and needs as these compare with information provided in the service description. Service providers  
 1866 offer capabilities that have real world effects that result in a change in state. Reachability of the service by  
 1867 the consumer may lead to interactions that change the state of the SOA ecosystem. The consumer can  
 1868 measure the change of state to determine if the claims made by description and the real world effects of  
 1869 consuming the service meet the consumer's needs.

1870  
 1871

1872  
 1873

Figure 24 - Visibility to Business

1874 Visibility and interoperability in a SOA ecosystem requires more than location and interface information. A  
 1875 meta-model for this broader view of visibility is depicted in Section 4.1. In addition to providing improved  
 1876 awareness of service capabilities through description of information such as reachability, behavior  
 1877 models, information models, functionality, and metrics, the service description may identify policies  
 1878 valuable for determination of willingness to interact.

1879 A mediator using service descriptions may provide event notifications to both consumers and providers  
 1880 about information relating to the descriptions. One example of this is a publish/subscribe model where the  
 1881 mediator allows consumers to subscribe to service description version changes made by the provider.  
 1882 Likewise, the mediator may provide notifications to the provider of consumers that have subscribed to  
 1883 service description updates.

1884 Another important characteristic of a SOA ecosystem is the ability to narrow visibility to trusted members  
 1885 within a social structure. Mediators for awareness may provide policy based access to service  
 1886 descriptions allowing for the dynamic formation of awareness between trusted members.

1887 **4.2.2 Visibility**

1888 Attaining visibility is described in terms of steps that lead to visibility. Different participant communities can  
 1889 bring different contexts for visibility within a single social structure, and the same general steps can be  
 1890 applied to each of the contexts to accomplish visibility.

1891 Attaining SOA visibility requires

1892       • service description creation and maintenance,  
1893       • processes and mechanisms for achieving awareness of and accessing descriptions,  
1894       • processes and mechanisms for establishing willingness of participants,  
1895       • processes and mechanisms to determine reachability.  
1896       Visibility may occur in stages, i.e. a participant can become aware enough to look or ask for further  
1897       description, and with this description, the participant can decide on willingness, possibly requiring  
1898       additional description. For example, if a potential consumer has a need for a tree cutting (business)  
1899       service, the consumer can use a web search engine to find web sites of providers. The web search  
1900       engine (a mediator) gives the consumer links to relevant web pages and the consumer can access those  
1901       descriptions. For those prospective providers that satisfy the consumer's criteria, the consumer's  
1902       willingness to interact increases. The consumer may contact several tree services to get detailed cost  
1903       information (or arrange for an estimate) and may ask for references (further description). The consumer is  
1904       likely to establish full visibility and proceed with interaction with the tree service that mutually establishes  
1905       visibility.

#### 1906       **4.2.2.1 Awareness**

1907       An important means for one participant to be aware of another is to have access to a description of that  
1908       participant and for the description to be sufficiently complete to support the other requirements of visibility.

1909       Awareness can be established without any action on the part of the target participant other than the target  
1910       providing appropriate descriptions. Awareness is often discussed in terms of consumer awareness of  
1911       providers but the concepts are equally valid for provider awareness of consumers.

1912       Awareness can be decomposed into: creating the descriptions, making them available, and discovering  
1913       the descriptions. Discovery can be initiated or it can be by notification.

1914       Achieving awareness in a SOA ecosystem can range from word of mouth to formal service descriptions in  
1915       a standards-based registry/repository. Some other examples of achieving awareness in a SOA  
1916       ecosystem are the use of a web page containing description information, email notifications of  
1917       descriptions, and document based descriptions.

1918       A mediator for awareness is a third party participant whose use provides awareness to one or more  
1919       consumers of one or more services. Direct awareness is awareness between a consumer and provider  
1920       without the use of a third party. The use of a registry/repository can provide awareness as can a Web  
1921       page displaying similar information.

1922       Direct awareness may be the result of having previously established an execution context, or direct  
1923       awareness may include determining the presence of services and then querying the service directly for  
1924       description. As an example, a priori visibility of some sensor device may provide the means for interaction  
1925       or a query for standardized sensor device metadata may be broadcast to multiple locations. If  
1926       acknowledged, the service interface for the device may directly provide description to a consumer so the  
1927       consumer can determine willingness to interact.

1928       The same medium for awareness may be direct in one context and may be mediated in another context.  
1929       For example, a service provider may maintain a web site with links to the provider's descriptions of  
1930       services giving the consumers direct awareness to the provider's services. Alternatively, a community  
1931       may maintain a web site with a search interface that makes use of an index of these (and possibly other)  
1932       descriptions of services, and the web site could be used by any number of consumers. More than one  
1933       approach to mediation may be involved, as different sources of description may specialize in different  
1934       functions whose use provides mediation.

1935       Descriptions may be formal or informal. Section 4.1, provides a comprehensive model for service  
1936       description that can be used to mediate visibility. Using consistent description taxonomies and standards  
1937       based mediated awareness helps provide more effective awareness.

#### 1938       **4.2.2.1.1 Mediated Awareness**

1939       Mediated awareness promotes simplification of the overall services infrastructure. Rather than all  
1940       potential service consumers being informed on a continual basis about all services, there is a known or  
1941       agreed upon facility or location that stores and supports discovery and/or notification related to the  
1942       service description.

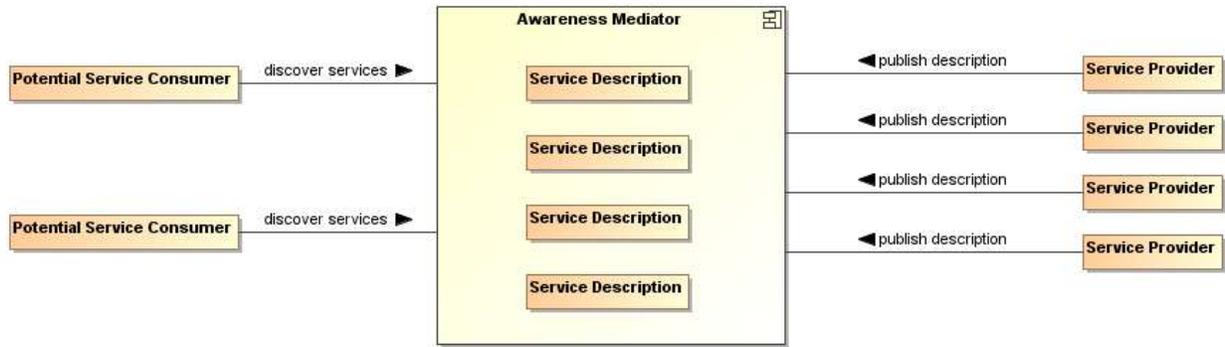

Figure 25 - Mediated Awareness

1943  
1944

1945 In *Figure 25*, the potential service consumers perform queries or are notified in order to locate those  
1946 services that satisfy their needs. As an example, the telephone book is a mediating registry where  
1947 individuals perform manual searches to locate services (i.e. the yellow pages). The telephone book is  
1948 also a mediated registry for solicitors to find and notify potential customers (i.e. the white pages).

1949 In mediated service awareness for large and dynamic numbers of service consumers and service  
1950 providers, the benefits of utilizing the awareness mediator typically far outweigh the management issues  
1951 associated with it. Some of the benefits of mediated service awareness are

- 1952 • Potential service consumers have a known location for searching thereby eliminating needless  
1953 and random searches
- 1954 • Typically a consortium of interested parties (or a sufficiently large corporation) serves as the host  
1955 of the mediation facility
- 1956 • Standardized tools and methods can be developed and promulgated to promote interoperability  
1957 and ease of use.

1958 However, mediated awareness can have some risks associated with it:

- 1959 • A single point of failure. If the awareness mediator fails then a large number of service providers  
1960 and consumers are potentially adversely affected.
- 1961 • A single point of control. If the awareness mediator is owned by, or controlled by, someone other  
1962 than the service consumers and/or providers then the latter may be put at a competitive  
1963 disadvantage based on policies of the discovery provider.

1964 A common mechanism for mediated awareness is a registry/repository. The registry stores links or  
1965 pointers to service description artifacts. The repository in this example is the storage location for the  
1966 service description artifacts. Service descriptions can be pushed (publish/subscribe for example) or pulled  
1967 from the registry/repository mediator.

1968 Registries/repositories may be referred to as federated when supported functions, such as responding to  
1969 discovery requests, are distributed across multiple registry/repository instances.

#### 1970 4.2.2.1.2 Awareness in Complex Social Structures

1971 Awareness applies to one or more social structures where there is at least one description provider and  
1972 one description consumer. Awareness may occur within the same social structure or across social  
1973 structures.

1974 In *Figure 26*, awareness can be between a limited set of consumers and providers within a single social  
1975 structure. Within a social structure, awareness can be encouraged or restricted through policies and  
1976 these policies can affect participant willingness. The information about policies should be incorporated in  
1977 the relevant descriptions. Additionally, the conditions for establishing contracts are governed within a  
1978 social structure.

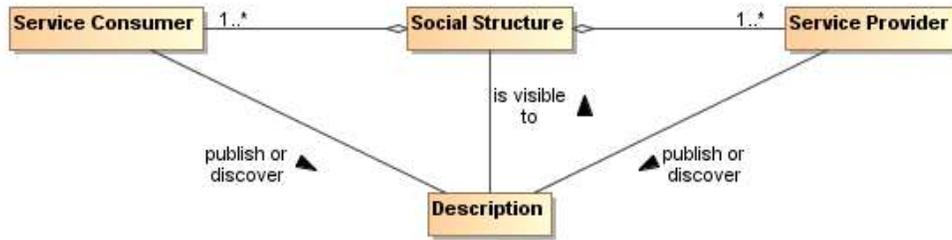

Figure 26 - Awareness in a SOA Ecosystem

1979  
1980

1981 IT policy/contract mechanisms can be used by visibility mechanisms to provide awareness between social  
1982 structures, including trust mechanisms to enable awareness between trusted social structures. For  
1983 example, government organizations may want to limit awareness of an organization's services to specific  
1984 communities of interest.

1985 Another common business model for awareness is maximizing awareness to those within the social  
1986 structure, the traditional market place business model. A centralized awareness-mediator often arises as  
1987 a provider for this global visibility, a gatekeeper of visibility so to speak. For example, Google is a  
1988 centralized awareness-mediator for accessing information on the web. As another example, television  
1989 networks have centralized entities providing a level of awareness to communities that otherwise could not  
1990 be achieved without going through the television network.

1991 However, mediators have motivations, and they may be selective in which information they choose to  
1992 make available to potential consumers. For example, in a secure environment, the mediator may enforce  
1993 security policies and make information selectively available depending on the security clearance of the  
1994 consumers.

#### 1995 4.2.2.2 Willingness

1996 Having achieved awareness, participants use descriptions to help determine their willingness to interact  
1997 with another participant. Both awareness and willingness are determined prior to consumer/provider  
1998 interaction.

1999 **Error! Reference source not found.**By establishing a willingness to interact within a particular social  
2000 structure (see Section 3.2.5.1 ), the social structure provides the participant access to capabilities based  
2001 on conditions the social structure finds appropriate for its context. The participant can use these  
2002 capabilities to satisfy goals and objectives as specified by the participant's needs.

2003 Information used to determine willingness is provided by Description (see Section 4.1.1). Information  
2004 referenced by Description may come from many sources. For example, a mediator for descriptions may  
2005 provide 3rd party annotations for reputation. Another source for reputation may be a participant's own  
2006 history of interactions with another participant. The contribution of real world effects to providing evidence  
2007 and establishing the reputation of a participant is discussed with relation to Figure 9.

2008 A participant inspects functionality for potential satisfaction of needs. Identity is associated with any  
2009 participant, however, identity may or may not be verified. If available, participant reputation may be a  
2010 deciding factor for willingness to interact. Policies and contracts referenced by the description may be  
2011 particularly important to determine the agreements and commitments required for business interactions.  
2012 Provenance may be used for verification of authenticity of a resource.

2013 Mechanisms that aid in determining willingness make use of the artifacts referenced by descriptions of  
2014 services. Mechanisms for establishing willingness could be as simple as rendering service description  
2015 information for human consumption to automated evaluation of functionality, policies, and contracts by a  
2016 rules engine. The rules engine for determining willingness could operate as a policy decision procedure  
2017 as defined in Section 4.4.

#### 2018 4.2.2.3 Reachability

2019 Reachability involves knowing the endpoint, protocol, and presence of a service. At a minimum,  
2020 reachability requires information about the location of the service and the protocol describing the means  
2021 of communication.

### Endpoint

A reference-able entity, processor or **resource** against which an **action** can be performed.

### Protocol

A structured means by which details of a service interaction mechanism are defined.

### Presence

The measurement of reachability of a service at a particular point in time.

A protocol defines a structured method of communication. Presence is determined by interaction through a communication protocol. Presence may not be known in many cases until the interaction begins. To overcome this problem, IT mechanisms may make use of presence protocols to provide the current up/down status of a service.

Service reachability enables service participants to locate and interact with one another. Each action may have its own endpoint and also its own protocols associated with the endpoint and whether there is presence for the action through that endpoint. Presence of a service is an aggregation of the presence of the service's actions, and the service level may aggregate to some degraded or restricted presence if some action presence is not confirmed. For example, if error processing actions are not available, the service can still provide required functionality if no error processing is needed. This implies reachability relates to each action as well as applying to the service/business as a whole.

## 4.2.3 Architectural Implications

Visibility in a SOA ecosystem has the following architectural implications on mechanisms providing support for awareness, willingness, and reachability:

- Mechanisms providing support for awareness **MUST** have the following minimum capabilities:
  - creation of Description, preferably conforming to a standard Description format and structure;
  - publishing of Description directly to a consumer or through a third party mediator;
  - discovery of Description, preferably conforming to a standard for Description discovery;
  - notification of Description updates or notification of the addition of new and relevant Descriptions;
  - classification of Description elements according to standardized classification schemes.
- In a SOA ecosystem with complex social structures, awareness **MAY** be provided for specific communities of interest. The architectural mechanisms for providing awareness to communities of interest **MUST** support:
  - policies that allow dynamic formation of communities of interest;
  - trust that awareness can be provided for and only for specific communities of interest, the bases of which are typically built on encryption technologies.
- The architectural mechanisms for determining willingness to interact **MUST** support:
  - verification of identity and credentials of the provider and/or consumer;
  - access to and understanding of description;
  - inspection of functionality and capabilities;

- 2062 ○ inspection of policies and/or contracts.
- 2063 • The architectural mechanisms for establishing reachability **MUST** support:
- 2064 ○ the location or address of an endpoint;
- 2065 ○ verification and use of a service interface by means of a communication protocol;
- 2066 ○ determination of presence with an endpoint which **MAY** only be determined at the point of
- 2067 interaction but **MAY** be further aided by the use of a presence protocol for which the
- 2068 endpoints actively participate.

## 2069 4.3 Interacting with Services Model

2070 Interaction is the activity involved in using a service to access capability in order to achieve a particular  
2071 desired real world effect, where real world effect is the actual result of using a service. An interaction can  
2072 be characterized by a sequence of communicative actions. Consequently, interacting with a service, i.e.  
2073 participating in joint action with the service—usually accomplished by a series of message exchanges—  
2074 involves individual actions performed by both the service and the consumer.<sup>7</sup> Note that a participant (or  
2075 delegate acting on behalf of the participant) can be the sender of a message, the receiver of a message,  
2076 or both.

### 2077 4.3.1 Interaction Dependencies

2078 Recall from the Reference Model that service visibility is the capacity for those with needs and those with  
2079 capabilities to be able to interact with each other, and that the service interface is the means by which the  
2080 underlying capabilities of a service are accessed. Ideally, the details of the underlying service  
2081 implementation are abstracted away by the service interface. (Service) interaction therefore has a direct  
2082 dependency on the visibility of the service as well as its implementation-neutral interface (see *Figure 28*).  
2083 Service visibility is composed of awareness, willingness, and reachability, and these are discussed in  
2084 Section 4.2. The information related to the service interface description is discussed in Section 4.1.1.3.1,  
2085 and the specifics of interaction are detailed in the remainder of Section 4.3. Service visibility is modeled in  
2086 Section 4.2.2.

---

<sup>7</sup> In order for multiple actors to participate in a joint action, they must each act according to their role within the joint action. For SOA-based systems, this is achieved through a message exchange style of communication. The concept of “joint action” is further described in Section 3.3.2.

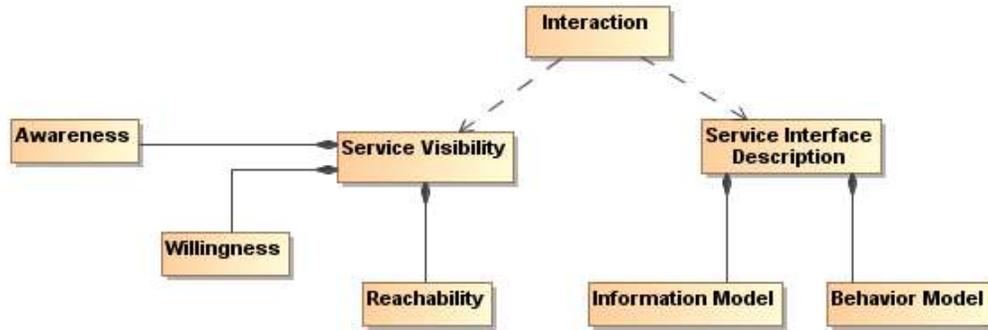

Figure 28 - Interaction dependencies

2087  
2088

### 2089 4.3.2 Actions and Events

2090 The SOA-RAF uses message exchange between service participants to denote actions performed  
 2091 against and by the service, and to denote events that report on real world effects that are caused by the  
 2092 service actions. A visual model of the relationship between these concepts is shown in Figure 29.

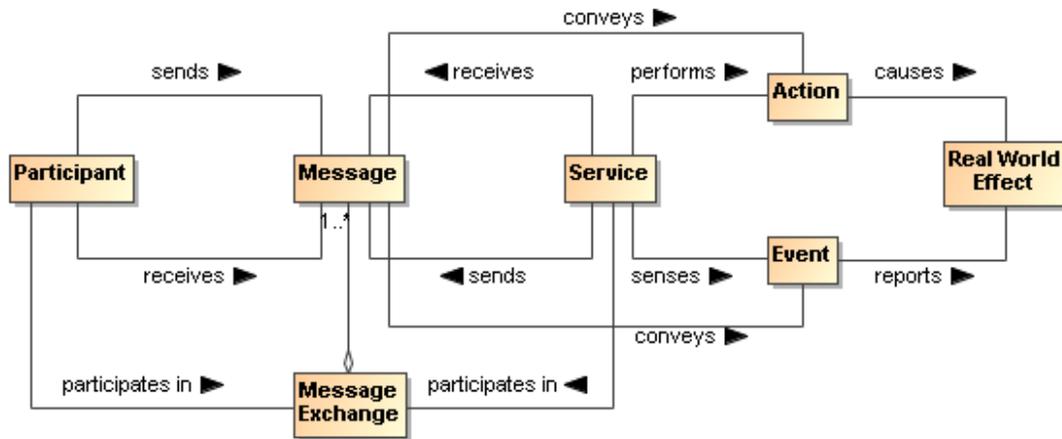

Figure 29 - A 'message' denotes either an action or an event

2093  
2094

2095 Both actions and events, realized by the SOA services, are denoted by the messages. The Reference  
 2096 Model states that the action model characterizes the “permissible set of actions that may be invoked  
 2097 against a service.” We extend that notion here to include events and that messages are intended for  
 2098 invoking actions or for notification of events.

2099 In Section 3.3.2 we saw that participants interact with each other in order to participate in joint actions. A  
 2100 joint action is not itself the same thing as the result of the joint action. When a joint action is participated in  
 2101 with a service, the real world effect that results may be reported in the form of an event notification.

### 2102 4.3.3 Message Exchange

2103 *Message exchange* is the means by which service participants (or their delegates) interact with each  
2104 other. There are two primary modes of interaction: joint actions that cause real world effects and  
2105 notification of events that report real world effects<sup>8</sup>.

2106 A message exchange is used to affect an action when the messages contain the appropriately formatted  
2107 content, are directed towards a particular action in accordance with the action model, and the delegates  
2108 involved interpret the message appropriately.

2109 A message exchange is also used to communicate event notifications. An event is an occurrence that is  
2110 of interest to some participant; in our case when some real world effect has occurred. Just as action  
2111 messages have formatting requirements, so do event notification messages. In this way, the Information  
2112 Model of a service must specify the syntax (structure), and semantics (meaning) of the action messages  
2113 and event notification messages as part of a service interface. It must also specify the syntax and  
2114 semantics of any data that is carried as part of a payload of the action or event notification message. The  
2115 Information Model is described in greater detail in the Service Description Model (see Section 4.1).

2116 In addition to the Information Model that describes the syntax and semantics of the messages and data  
2117 payloads, exception conditions and error handling in the event of faults (e.g., network outages, improper  
2118 message formats, etc.) must be specified or referenced as part of the Service Description.

2119 When a message is used to invoke an action, the correct interpretation typically requires the receiver to  
2120 perform an operation, which itself invokes a set of private, internal actions. These **operations** represent  
2121 the sequence of (private) actions a service must perform in order to validly participate in a given joint  
2122 action.

2123 Similarly, the correct consequence of realizing a real world effect may be to initiate the reporting of that  
2124 real world effect via an event notification.

#### 2125 **Message Exchange**

2126 The means by which **joint action** and event notifications are coordinated by service **participants**  
2127 (or **delegates**).

#### 2128 **Operations**

2129 The sequence of **actions** a service must perform in order to validly participate in a given **joint**  
2130 **action**.

### 2131 4.3.3.1 Message Exchange Patterns (MEPs)

2132 The basic temporal aspect of service interaction can be characterized by two fundamental message  
2133 exchange patterns (MEPs):

- 2134 • Request/response to represent how actions cause a real world effect
- 2135 • Event notification to represent how events report a real world effect

2136 This is by no means a complete list of all possible MEPs used for inter- or intra-enterprise messaging but  
2137 it does represent those that are most commonly used in exchange of information and reporting changes  
2138 in state both within organizations and across organizational boundaries.

---

<sup>8</sup> The notion of “joint” in joint action implies that you have to have a speaker *and* a listener in order to interact.

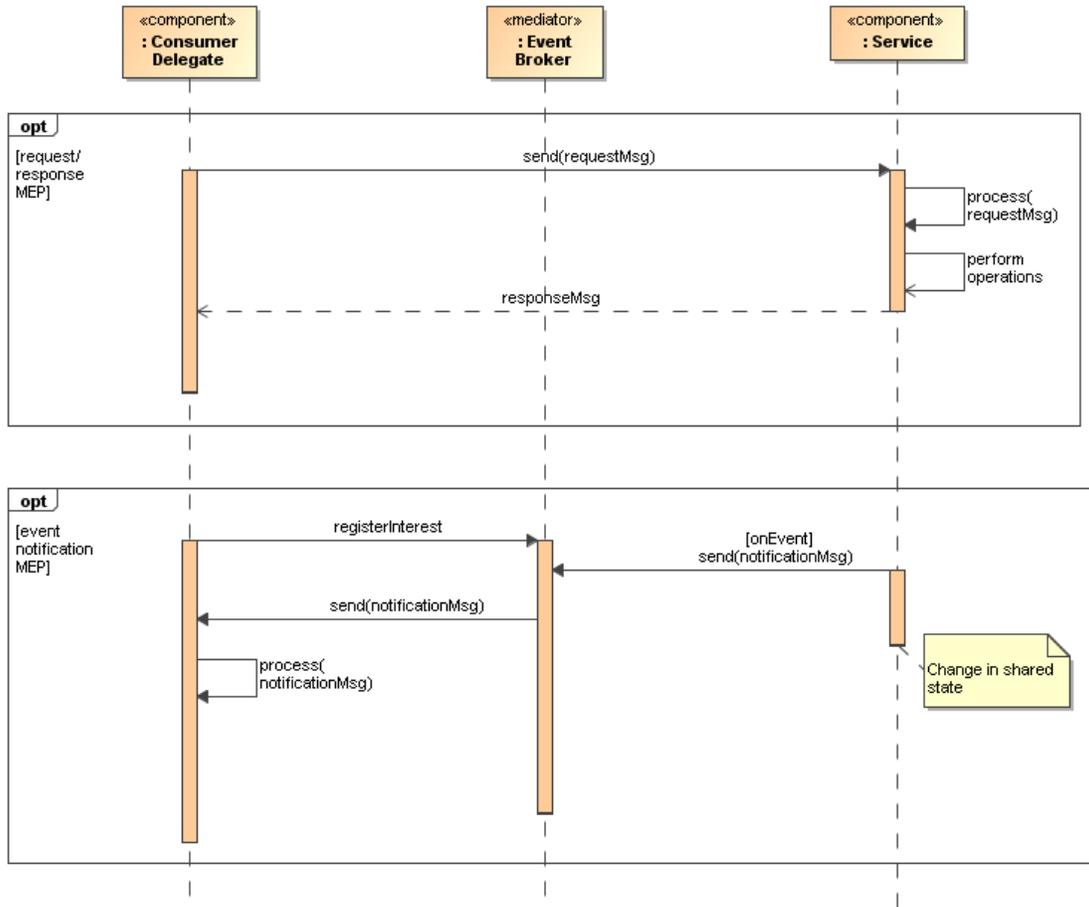

Figure 30 - Fundamental SOA message exchange patterns (MEPs)

2139  
2140

2141 Recall from the Reference Model that the Process Model characterizes “the temporal relationships  
2142 between and temporal properties of actions and events associated with interacting with the service.”  
2143 Thus, MEPs are a key element of the Process Model. The meta-level aspects of the Process Model (just  
2144 as with the Action Model) are provided as part of the Service Description Model (see Section 4.1).

2145 In the UML sequence diagram shown in Figure 30 it is assumed that the service participants (consumer  
2146 and provider) have delegated message handling to hardware or software delegates acting on their behalf.  
2147 In the case of the service consumer, this is represented by the *Consumer Delegate* component. In the  
2148 case of the service provider, the delegate is represented by the *Service* component. The message  
2149 interchange model illustrated represents a logical view of the MEPs and not a physical view. In other  
2150 words, specific hosts, network protocols, and underlying messaging system are not shown, as these tend  
2151 to be implementation specific. Although such implementation-specific elements are considered outside  
2152 the scope of this document, they are important considerations in modeling the SOA execution context.  
2153 Recall from the Reference Model that the *execution context* of a service interaction is “the set of  
2154 infrastructure elements, process entities, policy assertions and agreements that are identified as part of

2155 an instantiated service interaction, and thus forms a path between those with needs and those with  
2156 capabilities.”

### 2157 **4.3.3.2 Request/Response MEP**

2158 In a request/response MEP, the Consumer Delegate component sends a request message to the Service  
2159 component. The Service component then processes the request message. Based on the content of the  
2160 message, the Service component performs the service operation and the associated private actions.  
2161 Following the completion of these operations, a response message is returned to the Consumer Delegate  
2162 component. The response could be that a step in a process is complete, the initiation of a follow-on  
2163 operation, or the return of requested information.<sup>9</sup>

2164 Although the sequence diagram shows a *synchronous* interaction (because the sender of the request  
2165 message, i.e., Consumer Delegate, is blocked from continued processing until a response is returned  
2166 from the Service) other variations of request/response are valid, including *asynchronous* (non-blocking)  
2167 interaction through use of queues, channels, or other messaging techniques.

2168 What is important to convey here is that the request/response MEP represents action, which causes a  
2169 real world effect, irrespective of the underlying messaging techniques and messaging infrastructure used  
2170 to implement the request/response MEP.

### 2171 **4.3.3.3 Event Notification MEP**

2172 An event is made visible to interested consumers by means of an event notification message exchange  
2173 that reports a real world effect; specifically, a change in shared state between service participants. The  
2174 basic event notification MEP takes the form of a one-way message sent by a notifier component (in this  
2175 case, the Service component) and received by components with an interest in the event (here, the  
2176 Consumer Delegate component).

2177 Often the sending component may not be fully aware of all the components that wish to receive the  
2178 notification; particularly in so-called publish/subscribe ('pub/sub') situations. In event notification message  
2179 exchanges, it is rare to have a tightly-coupled link between the sending and the receiving component(s)  
2180 for a number of practical reasons. One of the most common constraints for pub/sub messaging is the  
2181 potential for network outages or communication interrupts that can result in loss of notification of events.  
2182 Therefore, a third-party mediator component is often used to decouple the sending and receiving  
2183 components.

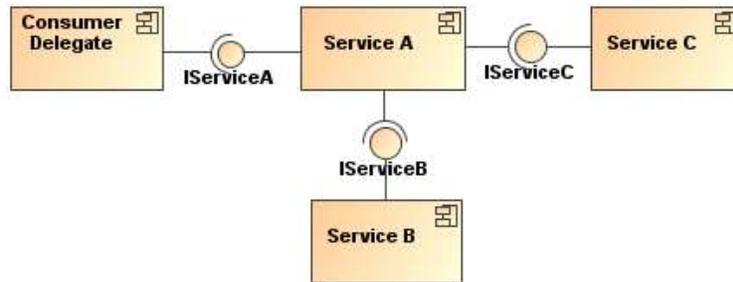

2184 Although this is typically an implementation issue, because this type of third-party decoupling is so  
2185 common in event-driven systems, it is warranted for use in modeling this type of message exchange in  
2186 the SOA-RAF. This third-party intermediary is shown in *Figure 30* as an Event Broker mediator. As with  
2187 the request/response MEP, no distinction is made between synchronous versus asynchronous  
2188 communication, although asynchronous message exchange is illustrated in the UML sequence diagram  
2189 depicted in *Figure 30*.

---

<sup>9</sup> There are cases when a response is not always desired and this would be an example of a “one-way” MEP. Similarly, while not shown here, there are cases when some type of “callback” MEP is required in which the consumer agent is actually exposed as a service itself and is able to process incoming messages from another service.

#### 2190 4.3.4 Composition of Services

2191 Composition of services is the act of aggregating or ‘composing’ a single service from one or more other  
2192 services. A simple model of service composition is illustrated in *Figure 31*.

2193  
2194

*Figure 31 - Simple model of service composition*

2195 Here, Service A is a service that has an exposed interface IServiceA, which is available to the Consumer  
2196 Delegate and relies on two other services in its implementation. The Consumer Delegate does not know  
2197 that Services B and C are used by Service A, or whether they are used in serial or parallel, or if their  
2198 operations succeed or fail. The Consumer Delegate only cares about the success or failure of Service A.  
2199 The exposed interfaces of Services B and C (IService B and IServiceC) are not necessarily hidden from  
2200 the Consumer Delegate; only the fact that these services are used as part of the composition of Service  
2201 A. In this example, there is no practical reason the Consumer Delegate could not interact with Service B  
2202 or Service C in some other interaction scenario.

2203 While the service composition is opaque from the Consumer Delegate’s perspective, it is transparent to  
2204 the service owner. This transparency is necessary for service management to properly manage the  
2205 dependencies between the services used in constructing the composite service—including managing the  
2206 service’s lifecycle. The subject of services as management entities is described and modeled in the  
2207 *Ownership in a SOA Ecosystem View* of the SOA-RAF and is not further elaborated in this section. The  
2208 point to be made here is that there can be different levels of opacity or transparency when it comes  
2209 to visibility of service composition.

2210 Services can be composed in a variety of ways, including direct consumer-to-service interaction, by using  
2211 programming techniques or using an intermediary, such as an orchestration engine leveraging higher  
2212 level orchestration languages. Such approaches are further elaborated in the following sub-sections.

#### 2213 4.3.5 Implementing Service Composition

2214 Services are implemented through a combination of processes and collaboration. The concepts involved  
2215 and that would be used in the context of exchanges both within and across organizational boundaries are  
2216 described and modeled as part of the *Participation in a SOA Ecosystem* view of this reference  
2217 architecture (see Section 3).

2218 The principles involved in the composition of services (including but not limited to loose coupling,  
2219 selective transparency and opacity, dynamic interactions) are equally applicable to services which  
2220 implement business processes and collaborations. Business processes and collaborations represent  
2221 complex, multi-step business functions that may involve multiple participants, including internal users,  
2222 external customers, and trading partners. Therefore, such complexities cannot simply be ignored when  
2223 transforming traditional business processes and collaborations to their service-oriented variants.

2224 While business processes are primarily concerned with describing how services are invoked and  
2225 executed, business collaborations are more concerned with how actors (usually from different  
2226 organizations) interact to realize a desired effect.

2227 Collaborations can include processes (for example, when one actor executes a particular activity  
2228 according to the predefined steps of a process) as much as processes can include collaborations (a  
2229 predefined step of a particular process may include agreed-upon activities provided by other participants).

2230 The techniques discussed below can be applied to any combination of services that instantiate service-  
2231 oriented business processes or service-oriented business collaborations.

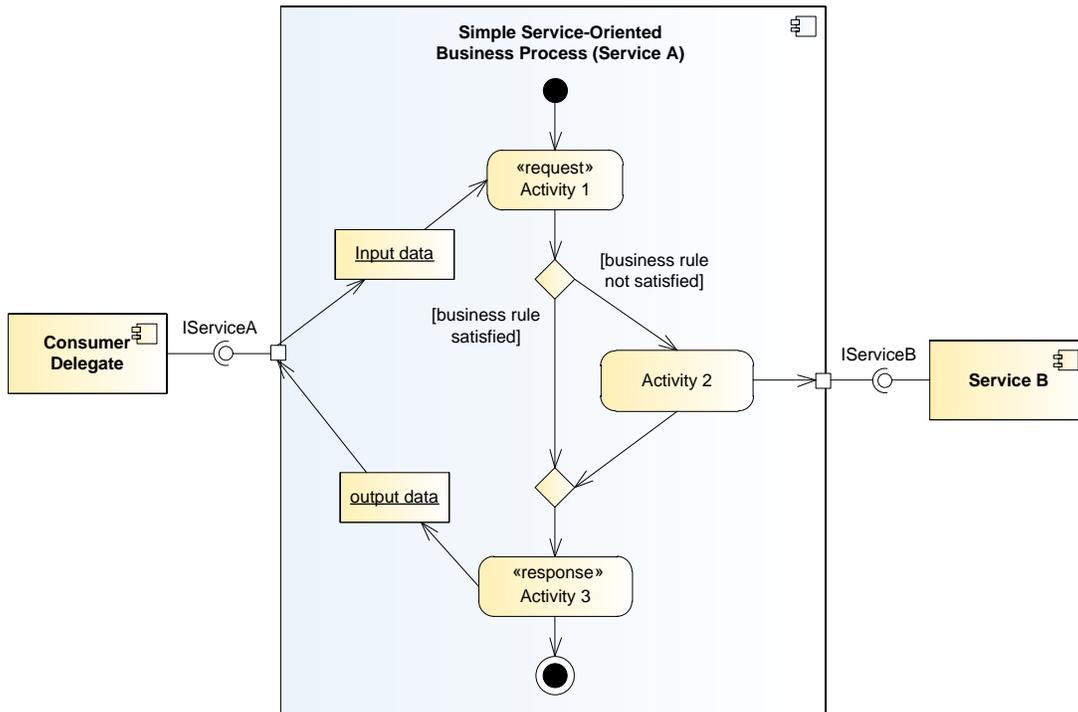

2232 **4.3.5.1 Service-Oriented Business Processes**

2233 Service orientation as applied to a business process includes

- 2234 • abstracting the set of activities and rules governing a business process; and
- 2235 • composing and exposing the resultant logic as a reusable service.

2236 When business processes are implemented as SOA services, all of the concepts used to describe and  
2237 model composition of services that were articulated in Section 4.3.4 apply.

2238 Business processes have temporal properties and can be short-lived or long-lived. Further, these  
2239 processes may involve many participants and may be important considerations for the consumer of a  
2240 service-oriented business process. For example, a consumer may need to know certain details of the  
2241 business process in order to have confidence in the resulting real world effects. For business processes  
2242 implemented as SOA-based services, ensuring that the meta-level aspects of the service-oriented  
2243 business process are included in its Service Description can provide needed insight for the consumer.

2244  
2245 *Figure 32 - Abstract example of a simple business process exposed as a service*

2246 In Figure 32, we use a UML activity diagram to model the simple service-oriented business process. This  
2247 allows us to capture the major elements, such as the set of related activities to be performed (an activity  
2248 being made up of one or more related actions, as explained in Section 3.3.2); the links between these  
2249 activities in a logical flow; data that is passed between activities, and any relevant business rules that  
2250 govern the transitions between the activities. While specific actions and activities can be readily modeled  
2251 in more detail, they are not illustrated in the model in Figure 32.

2252 This example is based on a request/response MEP and captures how one process can leverage  
2253 fulfillment of a particular activity (Activity 2) leverages by calling upon an externally-provided service,  
2254 Service B. The entire service-oriented business process is exposed as Service A that is accessible via its  
2255 externally visible interface, IServiceA. It is the availability of this external interface, and the description of  
2256 what the service intends, that distinguishes this from a simple business process.

2257 Although not explicitly shown in the model above, it is assumed that there exists a software or hardware  
2258 component that executes the process flow (Functionality of Service A). However, human actors may also  
2259 take part. This may be particularly important in cases where the automation fails and human intervention  
2260 becomes necessary.

2261 **4.3.5.2 Service-Oriented Business Collaborations**

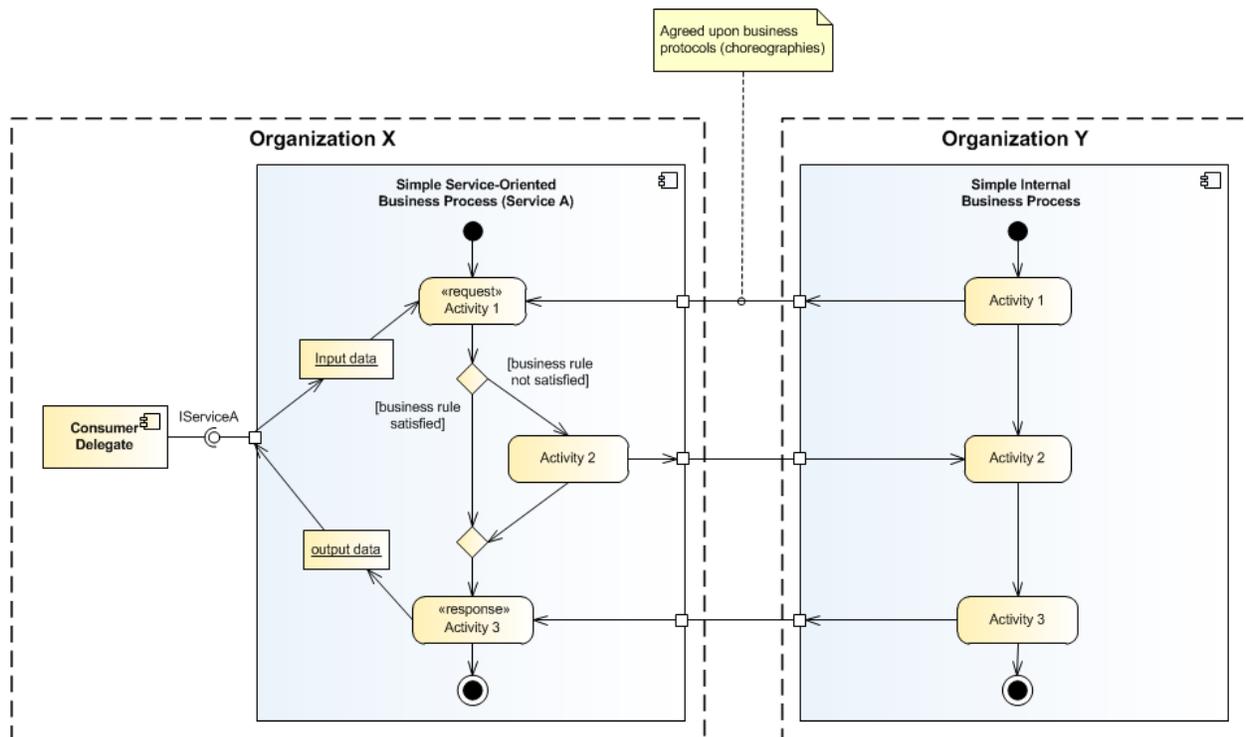

2262 Whereas a service can execute according to a predefined business process determined by one  
 2263 organization, service composition can also be accomplished as a cooperation, or business collaboration,  
 2264 between actors in different organizations and systems.

2265 In a service-oriented business collaboration, multiple participants interact in a peer-style communication  
 2266 as part of some larger business transaction by exchanging messages with trading partners and external  
 2267 organizations (e.g., suppliers) **[NEWCOMER/LOMOW]**. Participants do not necessarily expose the  
 2268 entirety of their respective capabilities but rather use service-based interactions to access those  
 2269 capabilities needed to fulfill the collaboration.

2270 Service-orientation as applied to a business collaboration includes:

- 2271 - ability of participants to individually provide and commit to what is required during an interaction for a
- 2272 collaboration to be successfully realized, including acceptance of preconditions and expected
- 2273 outcome;
- 2274 - availability of service functionality sufficient to realize the effects expected from the business
- 2275 collaboration;
- 2276 - willingness of participants to engage in interactions that are required as part of the collaboration;
- 2277 - availability of shared state and notifications to all participants who require them, such that they can
- 2278 fulfill their respective parts of the collaboration.

2279 Any service contributing to such a service-oriented business collaboration participates “as is”, without  
 2280 modification, and consistent with its own service description. Each contributing service is only an  
 2281 instrument in the collaboration and is not typically “aware” of its own contribution except as would be  
 2282 conveyed through inputs, access to shared states, or event notifications that are generally available to the  
 2283 service.

2284  
 2285 *Figure 33 - Abstract example of a more complex composition that relies on collaboration*

2286 *Figure 33*, which is a variant of the example illustrated earlier (in *Figure 32*), includes trust boundaries  
 2287 between two organizations; namely, Organization X and Organization Y. It is assumed that these two  
 2288 organizations are peer entities that have an interest in a business collaboration, for example,  
 2289 Organization X and Organization Y could be trading partners. Organization X retains the service-oriented  
 2290 business process Service A, which is exposed to internal consumers via its provided service interface,  
 2291 IServiceA. Organization Y also has a business process that is involved in the business collaboration; in

2292 this example, it is an internal business process but it could also be exposed to potential consumers either  
2293 within or outside its organizational boundary if it is designed as a reusable service in accordance with  
2294 SOA design principles.

2295 In *Figure 33*, the communications between Organization X and Organization Y are shown through ports  
2296 where there are “agreed-upon business protocols” that also cover the order in which activities are carried  
2297 out. These ports do not explicitly show service interfaces in order to emphasize that in the example these  
2298 are not intended to be generally available to any actor in the SOA ecosystem; however, the interfaces  
2299 should adhere to the principles involved in the composition of services.

2300 The message exchanges that are used need to specify how and when to initiate activity by the other  
2301 trading partner, i.e., communication between Organization X and Organization Y. Defining the business  
2302 protocols used in the business collaboration involves precisely specifying the visible message exchange  
2303 behavior and order of each of the parties involved in the protocol, without revealing internal  
2304 implementation details [NEWCOMER/LOMOW]. This is consistent with the Information and Behavior  
2305 Models discussed in the Reference Model and as part of service description in section 4.1.

2306 Business processes and collaboration are thus both facets of SOA service composition. The degree to  
2307 which one predominates over the other (and the mix of the two that emerges) will be a reflection of many  
2308 factors including the relative autonomy of participants and actors, the desired flexibility of a system, the  
2309 extent of trust involved and the assessment of risk, among others.

#### 2310 4.3.6 Architectural Implications of Interacting with Services

2311 Interacting with Services has the following architectural implications on mechanisms that facilitate service  
2312 interaction:

- 2313 • A well-defined service Information Model **MUST** be provided that:
  - 2314 ○ describes the syntax and semantics of the messages used to denote actions and events;
  - 2315 ○ describes the syntax and semantics of the data payload(s) contained within messages;
  - 2316 ○ documents exception conditions in the event of faults due to network outages, improper  
2317 message/data formats, etc.;
  - 2318 ○ is both human readable and machine processable;
  - 2319 ○ is referenceable from the Service Description artifact.
- 2320 • A well-defined service Behavior Model (as defined in the SOA-RM) **MUST** be provided that:
  - 2321 ○ characterizes the knowledge of the actions invoked against the service and events that  
2322 report real world effects as a result of those actions;
  - 2323 ○ characterizes the temporal relationships and temporal properties of actions and events  
2324 associated in a service interaction;
  - 2325 ○ describe activities involved in a workflow activity that represents a unit of work;
  - 2326 ○ describes the role (s) performed in a service-oriented business process or service-  
2327 oriented business collaboration;
  - 2328 ○ is both human readable and machine processable;
  - 2329 ○ is referenceable from the Service Description artifact.
- 2330 • Mechanisms **MUST** be included to support composition of service-oriented business processes and  
2331 service-oriented business collaborations such as:
  - 2332 ○ Declarative and programmatic compositional languages;
  - 2333 ○ Orchestration and/or choreography engines that support multi-step processes as part of a  
2334 short-lived or long-lived business transaction;
  - 2335 ○ Orchestration and/or choreography engines that support compensating transactions in  
2336 the presences of exception and fault conditions.
- 2337 • Infrastructure **MUST** be specified that provides mechanisms to support service interaction, including  
2338 but not limited to:
  - 2339 ○ mediation within service interactions based on shared semantics;
  - 2340 ○ translation and transformation of multiple application-level protocols to standard network  
2341 transport protocols;
  - 2342 ○ auditing and logging that provide a data store and mechanism to record information  
2343 related to service interaction activity such as message traffic patterns, security violations,  
2344 and service contract and policy violations

- 2345 ○ security that provides authorization and authentication support, etc., which provide
- 2346 protection against common security threats in a SOA ecosystem;
- 2347 ○ monitoring such as hardware and software mechanisms that both monitor the
- 2348 performance of systems that host services and network traffic during service interaction,
- 2349 and are capable of generating regular monitoring reports.
- 2350 ● In a service-oriented business collaboration, any language used **MUST** be capable of describing the
- 2351 coordination required of those service-oriented business processes that cross organizational
- 2352 boundaries. This **SHOULD** provide for contingencies, in case of an upset or when automation fails,
- 2353 including any necessary human intervention.

## 2354 4.4 Policies and Contracts Model

2355 A common phenomenon of many machines and systems is that the scope of potential behavior is much  
 2356 broader than is actually needed for a particular circumstance. This is especially true of a system as  
 2357 powerful as a SOA ecosystem. As a result, the behavior and performance of the system tend to be under-  
 2358 constrained by the implementation; instead, the actual behavior is expressed by means of policies of  
 2359 some form. Policies define the choices that stakeholders make; these choices are used to guide the  
 2360 actual behavior of the system to the desired behavior and performance.

2361 As noted in Section 3.2.5.2, a policy is an expression of constraints that is promulgated by a stakeholder  
 2362 who has the responsibility of ensuring that the constraint is enforceable. In contrast, contracts are  
 2363 **agreements** between participants.

2364 While responsibility for enforcement may differ, both contracts and policies share a common characteristic  
 2365 – there is a constraint that must be enforced. In both cases, the mechanisms needed to enforce  
 2366 constraints are likely to be identical; in this model, we focus on the issues involved in representing  
 2367 policies and contracts and on some of the principles behind their enforcement.

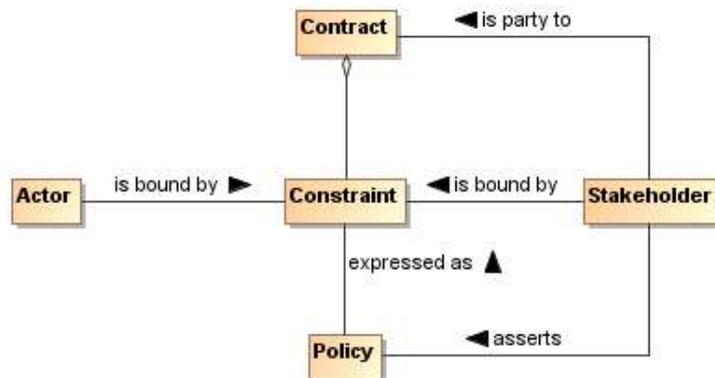

### 2368 4.4.1 Policy and Contract Representation

2369 A policy constraint is a specific kind of constraint: the ontology of policies and contracts includes the core  
 2370 concepts of permission, obligation, owner, and subject. In addition, it may be necessary to be able to  
 2371 combine policy constraints and to be able to resolve policy conflicts.

#### 2372 Policy Framework

2373 A policy framework is a language in which **policy constraints** may be expressed.

2374 A policy framework combines syntax for expressing policy constraints together with a decision procedure  
 2375 for determining if a policy constraint is satisfied.

2376  
2377 *Figure 34 - Policies and Contracts*

2378 We can characterize a policy framework in terms of a **logical framework** and an ontology of policies. The  
 2379 **policy ontology** details specific kinds of policy constraints that can be expressed; and the logical  
 2380 framework is a 'glue' that allows us to express combinations of policies.

2381 **Logical Framework**  
2382 A linguistic framework consisting of a syntax – a way of writing expressions – and a semantics –  
2383 a way of interpreting the expressions.

#### 2384 **Policy Ontology**

2385 A formalization of a set of concepts that are relevant to forming policy expressions.

2386 For example, a policy ontology that allows identification of simple constraints – such as the existence of a  
2387 property, or that a value of a property should be compared to a fixed value – is often enough to express  
2388 many basic constraints.

2389 Included in many policy ontologies are the basic signals of permissions and obligations. Some policy  
2390 frameworks are sufficiently constrained that there is no possibility of representing an obligation; in which  
2391 case there is often no need to ‘call out’ the distinction between permissions and obligations.

2392 The logical framework is also a strong determiner of the expressivity of the policy framework: the richer  
2393 the logical framework, the richer the set of policy constraints that can be expressed. However, there is a  
2394 strong inverse correlation such that increasing expressivity yields less ease and greater inefficiency of  
2395 implementation.

2396 In the discussion that follows we assume the following basic policy ontology:

#### 2397 **Policy Owner**

2398 A **stakeholder** that asserts and enforces the **policy**.

#### 2399 **Policy Subject**

2400 An **actor** whose action, or a **resource** whose maintenance or use, is constrained by a **policy**.

#### 2401 **Policy Constraint**

2402 A measurable and enforceable assertion found within a **policy**.

#### 2403 **Policy Object**

2404 An identifiable **state, action** or **resource** that is potentially constrained by the **policy**.

### 2405 **4.4.2 Policy and Contract Enforcement**

2406 The enforcement of policy constraints has to address two core problems: how to enforce the atomic policy  
2407 constraints, and how to enforce combinations of policy constraints. In addition, it is necessary to address  
2408 the resolution of policy conflicts. Contracts are the documented agreement between two or more parties  
2409 but otherwise have the same enforcement requirements as policies.

#### 2410 **4.4.2.1 Enforcing Simple Policy Constraints**

2411 The two primary kinds of policy constraint – permission and obligation – naturally lead to different styles  
2412 of enforcement. A permission constraint must typically be enforced prior to the policy subject invoking the  
2413 policy object. On the other hand, an obligation constraint must typically be enforced after the fact through  
2414 some form of auditing process and remedial action.

2415 For example, if a communications policy required that all communication be encrypted, this is enforceable  
2416 at the point of communication: any attempt to communicate a message that is not encrypted can be  
2417 blocked.

2418 Similarly, an obligation to pay for services rendered is enforced by ensuring that payment arrives within a  
2419 reasonable period of time. Invoices are monitored for prompt (or lack of) payment.

2420 The key concepts in enforcing both forms of policy constraint are the policy decision and the policy  
2421 enforcement.

#### 2422 **Policy Decision**

2423 A determination as to whether a given **policy constraint** is satisfied.

2424 A policy decision is effectively a measurement of some state – typically a portion of the SOA ecosystem’s  
2425 **shared state**. This implies a certain *timeliness* in the measuring: a measurement that is too early or is too  
2426 late does not actually help in determining if the policy constraint is satisfied appropriately.

#### 2427 **Policy Enforcement**

2428 A mechanism that limits the behavior and/or **state of policy subjects** to comply with a **policy**  
2429 **decision**.

2430 A policy enforcement implies the use of some mechanism to ensure compliance with a policy decision.  
2431 The range of mechanisms is completely dependent on the kinds of atomic policy constraints that the  
2432 policy framework may support. As noted above, the two primary styles of constraint – permission and  
2433 **obligation** –lead to different styles of enforcement.

### 2434 **4.4.2.2 Conflict Resolution**

2435 Whenever it is possible that more than one policy constraint applies in a given situation, there is the  
2436 potential that the policy constraints themselves are not mutually consistent. For example, a policy  
2437 constraint that requires communication to be encrypted and a policy constraint that requires an  
2438 administrator to read every communication conflict with each other – the two policy constraints cannot  
2439 both be satisfied concurrently.

2440 In general, with sufficiently rich policy frameworks, it is not possible to always resolve policy conflicts  
2441 automatically. However, a reasonable approach is to augment the policy decision process with simple  
2442 policy conflict resolution rules; with the potential for *escalating* a policy conflict to human adjudication.

#### 2443 **Policy Conflict**

2444 A state in a **policy decision** process in which the satisfaction of one or more **policy constraints**  
2445 leads directly to the violation of one or more other policy constraints.

#### 2446 **Policy Conflict Resolution**

2447 A **rule** determining which **policy constraint(s)** should prevail if a **policy conflict** occurs.

2448 The inevitable consequence of policy conflicts is that it is not possible to guarantee that all policy  
2449 constraints are satisfied at all times. This, in turn, implies certain *flexibility* in the application of policy  
2450 constraints: each individual constraint may not always be honored.

### 2451 **4.4.3 Architectural Implications**

2452 The key choices that must be made in a system of policies center on the policy framework, policy  
2453 enforcement, and conflict resolution

- 2454 • There **SHOULD** be a standard policy framework that is adopted across ownership domains within the  
2455 SOA ecosystem:
  - 2456 ○ This framework **MUST** permit the expression of simple policy constraints
  - 2457 ○ The framework **MAY** allow (to a varying extent) the combination of policy constraints,  
2458 including
    - 2459 • Both positive and negative constraints
    - 2460 • Conjunctions and disjunctions of constraints
    - 2461 • The quantification of constraints
  - 2462 ○ The framework **MUST** at least allow the policy subject and the policy object to be identified as  
2463 well as the policy constraint.
  - 2464 ○ The framework **MAY** allow further structuring of policies into modules, inheritance between  
2465 policies and so on.
- 2466 • There **SHOULD** be mechanisms that facilitate the application of policies:
  - 2467 ○ There **SHOULD** be mechanisms that allow policy decisions to be made, consistent with the  
2468 policy frameworks.
  - 2469 ○ There **SHOULD** be mechanisms to enforce policy decisions
    - 2470 • There **SHOULD** be mechanisms to support the measurement of whether certain  
2471 policy constraints are satisfied, or to what degree they are satisfied.

- 2472
- 2473
- 2474
- 2475
- 2476
- 2477
- 2478
- Such enforcement mechanisms **MAY** include support for both permission-style constraints and obligation-style constraints.
  - Enforcement mechanisms **MAY** support the simultaneous enforcement of multiple policy constraints across multiple points in the SOA ecosystem.
  - There **SHOULD** be mechanisms to resolve policy conflicts
    - This **MAY** involve escalating policy conflicts to human adjudication.
  - There **SHOULD** be mechanisms that support the management and promulgation of policies.

## 5 Ownership in a SOA Ecosystem View

*Governments are instituted among Men,  
deriving their just power from the consent of the governed  
American Declaration of Independence*

The *Ownership in a SOA Ecosystem View* focuses on the issues, requirements and responsibilities involved in owning a SOA-based system.

Ownership of a SOA-based system in a SOA ecosystem raises significantly different challenges to owning other complex systems – such as Enterprise suites – because there are strong limits on the control and authority of any one party when a system spans multiple ownership domains.

Even when a SOA-based system is deployed internally within an organization, there are multiple internal stakeholders involved and there may not be a simple hierarchy of control and management. Thus, an early consideration of how multiple boundaries affect SOA-based systems provides a firm foundation for dealing with them in whatever form they are found rather than debating whether the boundaries should exist.

This view focuses on the governance and management of SOA-based systems, on the security challenges involved in running a SOA-based system, and testing challenges.

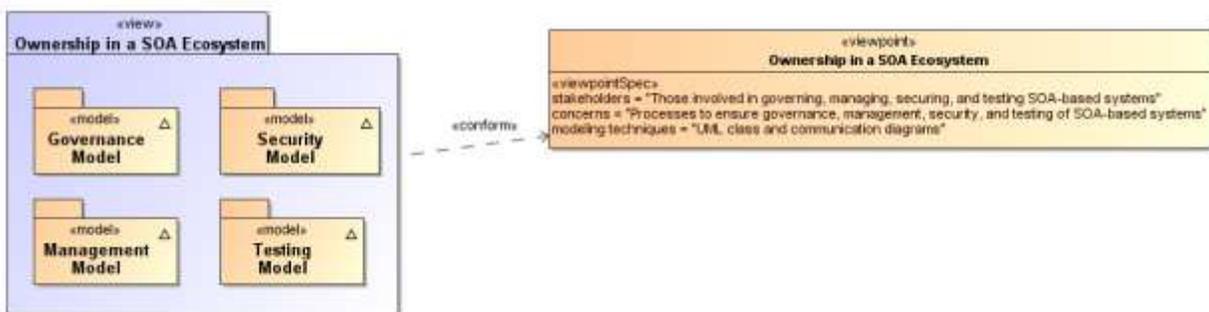

Figure 35 - Model Elements Described in the Ownership in a SOA Ecosystem View

The following subsections present models of these functions.

### 5.1 Governance Model

The Reference Model defines Service Oriented Architecture as an architectural paradigm for organizing and utilizing distributed capabilities that may be under the control of different ownership domains [SOA-RM]. Consequently, it is important that organizations that plan to engage in service interactions adopt governance policies and procedures sufficient to ensure that there is standardization across both internal and external organizational boundaries to promote the effective creation and use of SOA-based services.

#### 5.1.1 Understanding Governance

##### 5.1.1.1 Terminology

Governance is about making decisions that are aligned with the overall organizational strategy and culture of the enterprise. [HOTLE] It specifies the decision rights and accountability framework to encourage desirable behaviors [WEILL] towards realizing the strategy and defines incentives (positive or negative) towards that end. It is less about overt control and strict adherence to rules, and more about guidance and effective and equitable usage of resources to ensure sustainability of an organization's strategic objectives. [TOGAF v9]

2513 To accomplish this, governance requires organizational structure and processes and must identify who  
2514 has authority to define and carry out its mandates. It must address the following questions:

- 2515 1. what decisions must be made to ensure effective management and use?,
- 2516 2. who should make these decisions?,
- 2517 3. how will these decisions be made and monitored? , and
- 2518 4. how will these decisions be communicated?

2519 The intent is to achieve goals, add value, and reduce risk.

2520 Within a single ownership domain such as an enterprise, generally there is a hierarchy of governance  
2521 structures. Some of the more common enterprise governance structures include corporate governance,  
2522 technology governance, IT governance, and architecture governance **[TOGAF v9]**. These governance  
2523 structures can exist at multiple levels (global, regional, and local) within the overall enterprise.

2524 It is often asserted that SOA governance is a specialization of IT governance as there is a natural  
2525 hierarchy of these types of governance structures; however, the focus of SOA governance is less on  
2526 decisions to ensure effective management and use of IT as it is to ensure effective management and use  
2527 of SOA-based systems. Certainly, SOA governance must still answer the basic questions also associated  
2528 with IT governance, i.e., who should make the decisions, and how these decisions will be made and  
2529 monitored.

### 2530 **5.1.1.2 Relationship to Management**

2531 There is often confusion centered on the relationship between governance and management. As  
2532 described earlier, governance is concerned with decision making. Management, on the other hand, is  
2533 concerned with execution. Put another way, governance describes the world as **leadership** wants it to  
2534 be; management executes activities that intend to make the leadership's desired world a reality. Where  
2535 governance determines who has the authority and responsibility for making decisions and the  
2536 establishment of guidelines for how those decisions should be made, management is the actual process  
2537 of making, implementing, and measuring the impact of those decisions. Consequently, governance and  
2538 management work in concert to ensure a well-balanced and functioning organization as well as an  
2539 ecosystem of inter-related organizations. In the sections that follow, we elaborate further on the  
2540 relationship between governance and management in terms of setting and enforcing service policies,  
2541 contracts, and standards as well as addressing issues surrounding regulatory compliance.

### 2542 **5.1.1.3 Why is SOA Governance Important?**

2543 One of the hallmarks of SOA that distinguishes it from other architectural paradigms for distributed  
2544 computing is the ability to provide a uniform means to offer, discover, interact with and use capabilities  
2545 (as well the ability to compose new capabilities from existing ones) all in an environment that transcends  
2546 domains of ownership. Consequently, ownership, and issues surrounding it, such as obtaining acceptable  
2547 terms and conditions (T&Cs) in a contract, is one of the primary topics for SOA governance. Generally, IT  
2548 governance does not include T&Cs, for example, as a condition of use as its primary concern.

2549 Just as other architectural paradigms, technologies, and approaches to IT are subject to change and  
2550 evolution, so too is SOA. Setting policies that allow change management and evolution, establishing  
2551 strategies for change, resolving disputes that arise, and ensuring that SOA-based systems continue to  
2552 fulfill the goals of the business are all reasons why governance is important to SOA.

### 2553 **5.1.1.4 Governance Stakeholders and Concerns**

2554 As noted in Section 3.2.1 the participants in a service interaction include the service provider, the service  
2555 consumer, and other interested or unintentional third parties. Depending on the circumstances, it may  
2556 also include the owners of the underlying capabilities that the SOA services access. Governance must  
2557 establish the policies and rules under which duties and responsibilities are defined and the expectations  
2558 of participants are grounded. The expectations include transparency in aspects where transparency is  
2559 mandated; trust in the impartial and consistent application of governance; and assurance of reliable and  
2560 robust behavior throughout the SOA ecosystem.

2561 **5.1.2 A Generic Model for Governance**

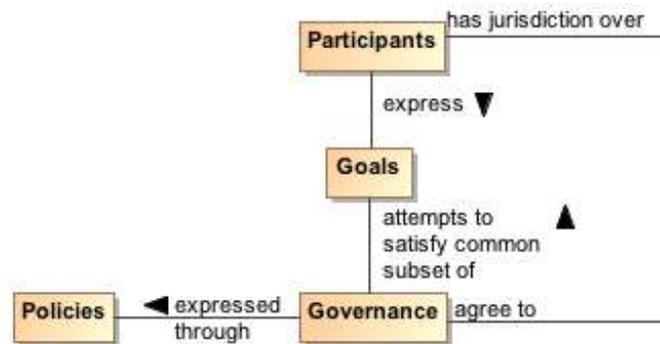

2562 **Governance**

2563 The prescription of conditions and constraints consistent with satisfying common goals and the  
2564 structures and processes needed to define and respond to actions taken towards realizing those  
2565 goals.

2566 The following is a generic model of governance represented by segmented models that begin with  
2567 motivation and proceed through measuring compliance. It is not all-encompassing but a focused subset  
2568 that captures the aspects necessary to describe governance for SOA. It does not imply that practical  
2569 application of governance is a single, isolated instance of these models; in reality, there may be  
2570 hierarchical and parallel chains of governance that deal with different aspects or focus on different goals.  
2571 This is discussed further in section 5.1.2.5. The defined models are simultaneously applicable to each of  
2572 the overlapping instances.

2573 A given enterprise may already have portions of these models in place. To a large extent, the models  
2574 shown here are not specific to SOA; discussions on direct applicability begin in section 5.1.3.

2575 **5.1.2.1 Motivating Governance**

2576  
2577 *Figure 36 - Motivating Governance*

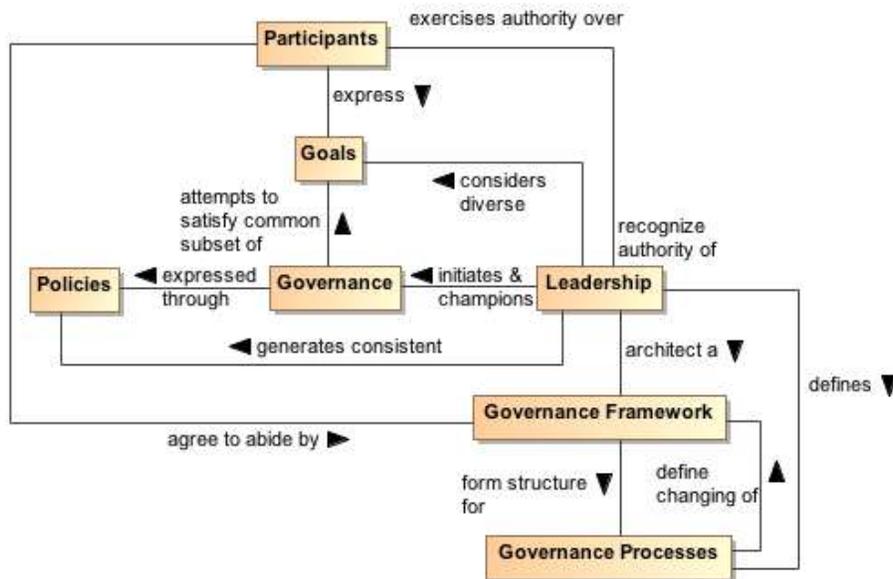

2578 An organizational domain such as an enterprise is made up of participants who may be individuals or  
2579 groups of individuals forming smaller organizational units within the enterprise. The overall business  
2580 strategy should be consistent with the goals of the participants; otherwise, the business strategy would  
2581 not provide value to the participants and governance towards those ends becomes difficult if not  
2582 impossible. This is not to say that an instance of governance simultaneously satisfies all the goals of all  
2583 the participants; rather, the goals of any governance instance must sufficiently satisfy a useful subset of  
2584 each participant's goals so as to provide value and ensure the cooperation of all the participants.

2585 A policy is the formal characterization of the conditions and constraints that governance deems as  
2586 necessary to realize the goals which it is attempting to satisfy. Policy may identify required conditions or  
2587 actions or may prescribe limitations or other constraints on permitted conditions or actions. For example,  
2588 a policy may prescribe that safeguards must be in place to prevent unauthorized access to sensitive  
2589 material. It may also prohibit use of computers for activities unrelated to the specified work assignment.  
2590 Policy is made operational through the promulgation and implementation of Rules and Regulations (as  
2591 defined in section 5.1.2.3).

2592 As noted in section 4.4.2, policy may be asserted by any participant or on behalf of the participant by its  
2593 organization. Part of the purpose of governance is to arbitrate among diverse goals of participants and  
2594 the diverse policies articulated to realize those goals. The intent is to form a consistent whole that allows  
2595 governance to minimize ambiguity about its purpose. While resolving all ambiguity would be an ideal, it is  
2596 unlikely that all inconsistencies will be identified and resolved before governance becomes operational.

2597 For governance to have effective jurisdiction over participants, there must be some degree of agreement  
2598 by all participants that they will abide by the governance mandates. A minimal degree of agreement often  
2599 presages participants who 'slow-roll' if not actively rejecting compliance with policies that express the  
2600 specifics of governance.

2601 **5.1.2.2 Setting Up Governance**

2602  
2603 *Figure 37 - Setting Up Governance*

2604 **Leadership**

2605 The entity having the **responsibility** and **authority** to generate consistent **policies** through which  
2606 the goals of **governance** can be expressed and to define and champion the structures and  
2607 processes through which governance is realized.

2608 **Governance Framework**

2609 The set of organizational structures that enable **governance** to be consistently defined, clarified,  
2610 and as needed, modified to respond to changes in its domain of concern.

2611 **Governance Process**

2612 The defined set of activities performed within the **Governance Framework** to enable the  
2613 consistent definition, application, and as needed, modification of **rules** that organize and regulate  
2614 the activities of **participants** for the fulfillment of expressed **policies**.

2615 See section 5.1.2.3 for elaboration on the relationship of Governance Processes and Rules.

2616 As noted earlier, governance requires an appropriate organizational structure and identification of who  
2617 has authority to make governance decisions. In *Figure 37*, the entity with governance authority is  
2618 designated the Leadership. This is someone, possibly one or more of the participants, which participants  
2619 recognize as having authority for a given purpose or over a given set of issues or concerns.

2620 The leadership is responsible for prescribing or delegating a working group to prescribe the governance  
2621 framework that forms the structure for governance processes that define how governance is to be carried  
2622 out. This does not itself define the specifics of how governance is to be applied, but it does provide an  
2623 unambiguous set of procedures that should ensure consistent actions which participants agree are fair  
2624 and account for sufficient input on the subjects to which governance is applied.

2625 The participants may be part of the working group that codifies the governance framework and  
2626 processes. When complete, the participants must acknowledge and agree to abide by the products  
2627 generated through application of this structure.

2628 The governance framework and processes are often documented in the constitution or charter of a body  
2629 created or designated to oversee governance. This is discussed further in the next section. Note that the  
2630 governance processes should also include those necessary to modify the governance framework itself.

2631 An important function of leadership is not only to initiate but also be the consistent champion of  
2632 governance. Those responsible for carrying out governance mandates must have leadership who make it

2633 clear to participants that expressed policies are seen as a means to realizing established goals and that  
2634 compliance with governance is required.

### 2635 5.1.2.3 Carrying Out Governance

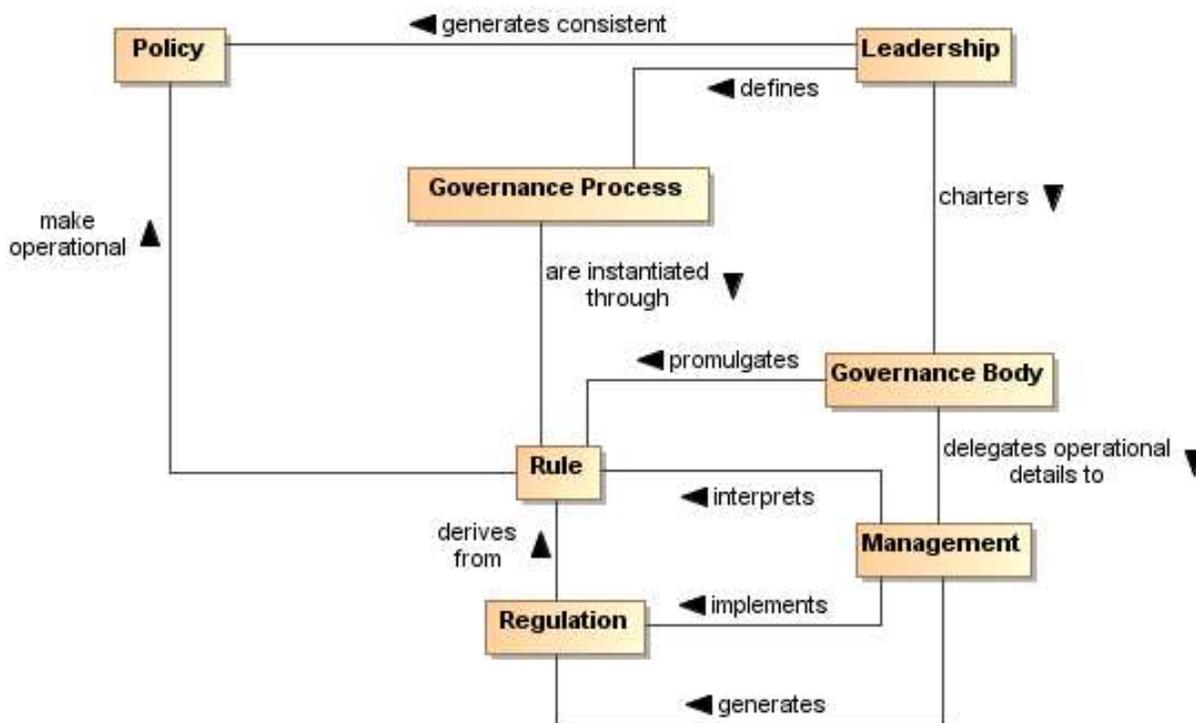

Figure 38 - Carrying Out Governance

2636

2637

#### 2638 Rule

2639 A prescribed guide for carrying out activities and processes leading to desired results, e.g. the  
2640 operational realization of **policies**.

#### 2641 Regulation

2642 A mandated process or the specific details that derive from the interpretation of **rules** and lead to  
2643 measureable quantities against which compliance can be measured.

2644 To carry out governance, leadership charts a governance body to promulgate the rules needed to make  
2645 the policies operational. The governance body acts in line with governance processes for its rule-making  
2646 process and other functions. Whereas governance is the setting of policies and defining the rules that  
2647 provide an operational context for policies, governance body may delegate the operational details of  
2648 governance to management. Management generates regulations that specify details for rules and other  
2649 procedures to implement both rules and regulations. For example, leadership could set a policy that all  
2650 authorized parties should have access to data, the governance body would promulgate a rule that PKI  
2651 certificates are required to establish identity of authorized parties, and management can specify a  
2652 regulation of who it deems to be a recognized PKI issuing body. In summary, policy is a predicate to be  
2653 satisfied and rules prescribe the activities by which that satisfying occurs. A number of rules may be  
2654 required to satisfy a given policy; the carrying out of a rule may contribute to several policies being  
2655 realized.

2656 Whereas the governance framework and processes are fundamental for having participants acknowledge  
2657 and commit to compliance with governance, the rules and regulations provide operational constraints that  
2658 may require resource commitments or other levies on the participants. It is important for participants to  
2659 consider the framework and processes to be fair, unambiguous, and capable of being carried out in a  
2660 consistent manner and to have an opportunity to formally accept or ratify this situation. rules and  
2661 regulations, however, do not require individual acceptance by any given participant although some level

2662 of community comment may be part of the governance processes. Having agreed to governance, the  
 2663 participants are bound to comply or be subject to prescribed mechanisms for enforcement.

2664 **5.1.2.4 Ensuring Governance Compliance**

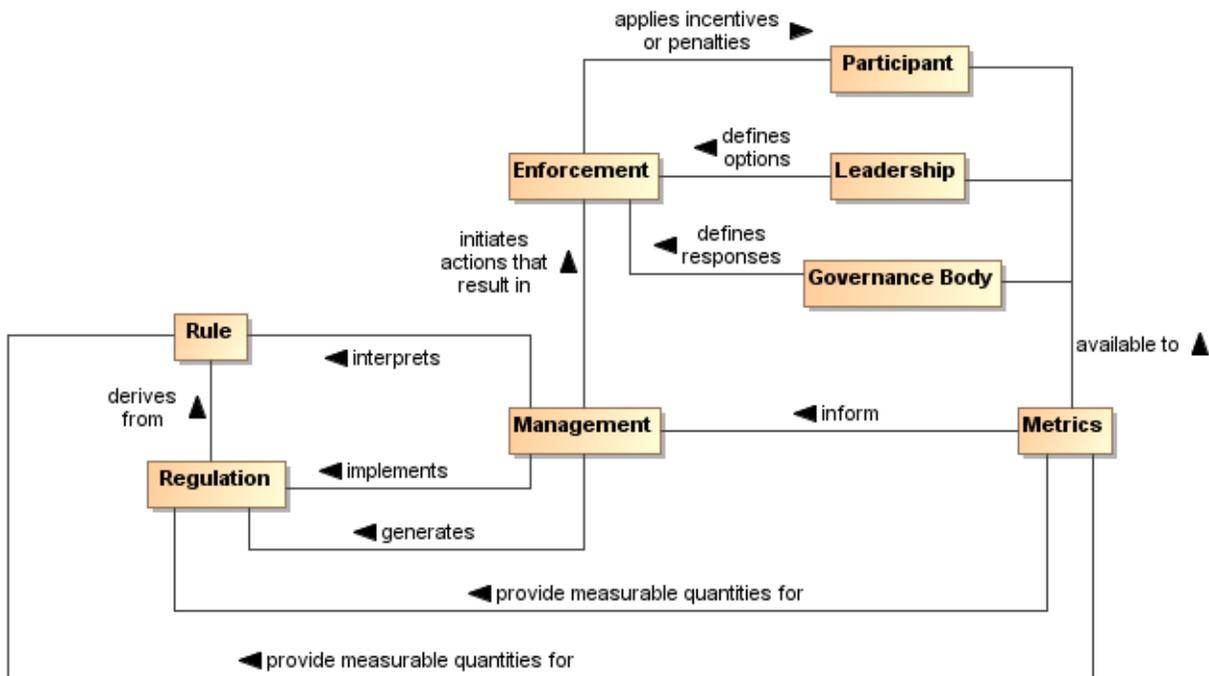

Figure 39 - Ensuring Governance Compliance

2665  
 2666  
 2667 Setting rules and regulations does not ensure effective governance unless compliance can be measured  
 2668 and rules and regulations can be enforced. Metrics are those conditions and quantities that can be  
 2669 measured to characterize actions and results. Rules and regulations must be based on collected metrics,  
 2670 or there is no means for management to assess compliance. The metrics are available to the participants,  
 2671 the leadership, and the governance body so what is measured and the results of measurement are clear  
 2672 to everyone.

2673 The leadership in its relationship with participants has certain options that can be used for enforcement. A  
 2674 common option may be to affect future funding. The governance body defines specific enforcement  
 2675 responses, such as what degree of compliance is necessary for full funding to be restored. It is up to  
 2676 management to identify compliance shortfalls and to initiate the enforcement process.

2677 Note, enforcement does not strictly need to be negative consequences. Management can use metrics to  
 2678 identify exemplars of compliance and leadership can provide options for rewarding the participants. The  
 2679 governance body defines awards or other incentives.

2680 **5.1.2.5 Considerations for Multiple Governance Chains**

2681 As noted in section 5.1.2, instances of the governance model often occur as a tiered arrangement, with  
 2682 governance at some level delegating specific authority and responsibility to accomplish a focused portion  
 2683 of the original level's mandate. For example, a corporation may encompass several lines of business and  
 2684 each line of business governs its own affairs in a manner that is consistent with and contributes to the  
 2685 goals of the parent organization. Within the line of business, an IT group may be given the mandate to  
 2686 provide and maintain IT resources, giving rise to IT governance.

2687 In addition to tiered governance, there may be multiple governance chains working in parallel. For  
 2688 example, a company making widgets has policies intended to ensure they make high quality widgets and  
 2689 make an impressive profit for their shareholders. On the other hand, Sarbanes-Oxley is a parallel  
 2690 governance chain in the United States that specifies how the management must handle its accounting

2691 and information that must be given to its shareholders. The parallel chains may just be additive or may be  
2692 in conflict and require some harmonization.

2693 Being distributed and representing different ownership domains, a SOA participant falls under the  
2694 jurisdiction of multiple governance domains simultaneously and may individually need to resolve  
2695 consequent conflicts. The governance domains may specify precedence for governance conformance or  
2696 it may fall to the discretion of the participant to decide on the course of actions they believe appropriate.

### 2697 **5.1.3 Governance Applied to SOA**

#### 2698 **5.1.3.1 Where SOA Governance is Different**

2699 SOA governance is often discussed in terms of IT governance, but rather than a parent-child relationship,  
2700 *Figure 40* shows the two as siblings within the general governance described in section 5.1.2. There are  
2701 obvious dependencies and a need for coordination between the two, but the idea of aligning IT with  
2702 business already demonstrates that resource providers and resource consumers must be working  
2703 towards common goals if they are to be productive and efficient. While SOA governance is shown to be  
2704 active in the area of infrastructure, it is a specialized concern for having a dependable platform to support  
2705 service interaction; a range of traditional IT issues is therefore out of scope of this document. A SOA  
2706 governance plan for an enterprise will not of itself resolve shortcomings with the enterprise's IT  
2707 governance.

2708 Governance in the context of SOA is that organization of services: that promotes their visibility; that  
2709 facilitates interaction among service participants; and that directs that the results of service interactions  
2710 are those real world effects as described within the service description and constrained by policies and  
2711 contracts as assembled in the execution context.

2712 SOA governance must specifically account for control across different ownership domains, i.e. all the  
2713 participants may not be under the jurisdiction of a single governance authority. However, for governance  
2714 to be effective, the participants must agree to recognize the authority of the governance body and must  
2715 operate within the Governance Framework and through the Governance Processes so defined.

2716 SOA governance must account for interactions across ownership boundaries, which may also imply  
2717 across enterprise governance boundaries. For such situations, governance emphasizes the need for  
2718 agreement that some governance framework and governance processes have jurisdiction, and the  
2719 governance defined must satisfy the goals of the participants for cooperation to continue. A standards  
2720 development organization such as OASIS is an example of voluntary agreement to governance over a  
2721 limited domain to satisfy common goals.

2722 The specifics discussed in the figures in the previous sections are equally applicable to governance  
2723 across ownership boundaries as it is within a single boundary. There is a charter agreed to when  
2724 participants become members of the organization, and this charter sets up the structures and processes  
2725 to be followed. Leadership may be shared by the leadership of the overall organization and the leadership  
2726 of individual groups themselves chartered per the governance processes. There are rules and regulations  
2727 specific to individual efforts for which participants agree to local goals, and enforcement can be loss of  
2728 voting rights or under extreme circumstances, expulsion from the group.

2729 Thus, the major difference for SOA governance is an appreciation for the cooperative nature of the  
2730 enterprise and its reliance on furthering common goals if productive participation is to continue.

#### 2731 **5.1.3.2 What Must be Governed**

2732 An expected benefit of employing SOA principles is the ability to quickly bring resources to bear to deal  
2733 with unexpected and evolving situations. This requires a great deal of confidence in the underlying  
2734 capabilities that can be accessed and in the services that enable the access. It also requires considerable  
2735 flexibility in the ways these resources can be employed. Thus, SOA governance requires establishing  
2736 confidence and trust (see Section 3.2.5.1) while instituting a solid framework that enables flexibility,  
2737 indicating a combination of strict control over a limited set of foundational aspects but minimum  
2738 constraints beyond those bounds.

2739

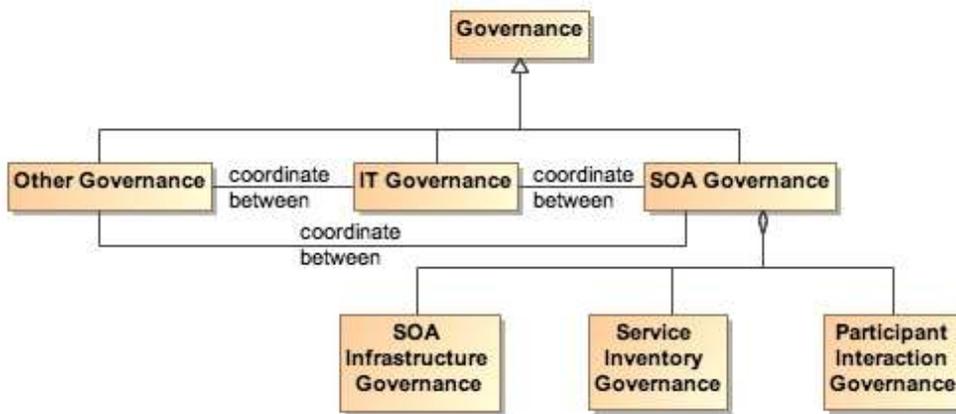

Figure 40 - Relationship Among Types of Governance

2740  
2741  
2742  
2743  
2744  
2745  
2746  
2747  
2748

SOA governance applies to three aspects of service definition and use:

- SOA infrastructure – the ‘plumbing’ that provides utility functions that enable and support the use of the service
- Service inventory – the requirements on a service to permit it to be accessed within the infrastructure
- Participant interaction – the consistent expectations with which all participants are expected to comply

#### 2749 5.1.3.2.1 Governance of SOA Infrastructure

2750 The SOA infrastructure is likely composed of several families of SOA services that provide access to  
2751 fundamental computing business services. These include, among many others, services such as  
2752 messaging, security, storage, discovery, and mediation. The provisioning of an infrastructure on which  
2753 these services may be accessed and the general realm of those contributing as utility functions of the  
2754 infrastructure are a traditional IT governance concern. In contrast, the focus of SOA governance is how  
2755 the existence and use of the services enables the SOA ecosystem.

2756 By characterizing the environment as containing families of SOA services, the assumption is that there  
2757 may be multiple approaches to providing the business services or variations in the actual business  
2758 services provided. For example, discovery could be based on text search, on metadata search, on  
2759 approximate matches when exact matches are not available, and numerous other variations. The  
2760 underlying implementation of search algorithms are not the purview of SOA governance, but the access  
2761 to the resulting service infrastructure enabling discovery must be stable, reliable, and extremely robust to  
2762 all operating conditions. Such access enables other specialized SOA services to use the infrastructure in  
2763 dependable and predictable ways, and is where governance is important.

#### 2764 5.1.3.2.2 Governance of the Service Inventory

2765 Given an infrastructure in which other SOA services can operate, a key governance issue is which SOA  
2766 services to allow in the ecosystem. The major concern should be a definition of well-behaved services,  
2767 where the required behavior will inherit their characteristics from experiences with distributed computing  
2768 but also evolve with SOA experience. A major need for ensuring well-behaved services is collecting  
2769 sufficient metrics to know how the service affects the SOA infrastructure and whether it complies with  
2770 established infrastructure policies.

2771 Another common concern of service approval is whether there is a possibility of duplication of function by  
2772 multiple services. Some governance models talk to a tightly controlled environment where a primary  
2773 concern is to avoid any service duplication. Other governance models talk to a market of services where  
2774 the consumers have wide choices. For the latter, it is anticipated that the better services will emerge from  
2775 market consensus and the availability of alternatives will drive innovation.

2776 Some combination of control and openness will emerge, possibly with a different appropriate balance for  
2777 different categories of use. For SOA governance, the issue is less which services are approved but rather  
2778 ensuring that sufficient description is available to support informed decisions for appropriate use. Thus,  
2779 SOA governance should concentrate on identifying the required attributes to adequately describe a  
2780 service, the required target values of the attributes, and the standards for defining the meaning of the  
2781 attributes and their target values. Governance may also specify the processes by which the attribute  
2782 values are measured and the corresponding certification that some realized attribute set may imply.

2783 For example, unlimited access for using a service may require a degree of life cycle maturity that has  
2784 demonstrated sufficient testing over a certain size community. Alternately, the policy may specify that a  
2785 service in an earlier phase of its life cycle may be made available to a smaller, more technically  
2786 sophisticated group in order to collect the metrics that would eventually allow the service to advance its  
2787 life cycle status.

2788 This aspect of governance is tightly connected to description because, given a well-behaved set of  
2789 services, it is the responsibility of the consumer (or policies promulgated by the consumer's organization)  
2790 to decide whether a service is sufficient for that consumer's intended use. The goal is to avoid global  
2791 governance specifying criteria that are too restrictive or too lax for local needs of which global governance  
2792 has little insight.

2793 Such an approach to specifying governance allows independent domains to describe services in local  
2794 terms while still having the services available for informed use across domains. In addition, changes to  
2795 the attribute sets within a domain can be similarly described, thus supporting the use of newly described  
2796 resources with the existing ones without having to update the description of the entire legacy content.

### 2797 **5.1.3.2.3 Governance of Participant Interaction**

2798 Finally, given a reliable services infrastructure and a predictable set of services, the third aspect of  
2799 governance is prescribing what is required during a service interaction.

2800 Governance would specify adherence to service interface and service reachability parameters and would  
2801 require that the result of an interaction correspond to the real world effects as contained in the service  
2802 description. Governance would ensure preconditions for service use are satisfied, in particular those  
2803 related to security aspects such as user authentication, authorization, and non-repudiation. If conflicts  
2804 arise, governance would specify resolution processes to ensure appropriate agreements, policies, and  
2805 conditions are met.

2806 It would also rely on sufficient monitoring by the SOA infrastructure to ensure services remain well-  
2807 behaved during interactions, e.g. do not use excessive resources or exhibit other prohibited behavior.  
2808 Governance would also require that policy agreements as documented in the execution context for the  
2809 interaction are observed and that the results and any after effects are consistent with the agreed policies.  
2810 Here, governance focuses more on contractual and legal aspects rather than the precursor descriptive  
2811 aspects. SOA governance may prescribe the processes by which SOA-specific policies are allowed to  
2812 change, but there are probably more business-specific policies that will be governed by processes  
2813 outside SOA governance.

### 2814 **5.1.3.3 Overarching Governance Concerns**

2815 There are numerous governance related concerns whose effects span the three areas just discussed.  
2816 One is the area of standards, how these are mandated, and how the mandates may change. The Web  
2817 Services standards stack is an example of relevant standards where a significant number are still under  
2818 development. In addition, while there are notional scenarios that guide what standards are being  
2819 developed, the fact that many of these standards do not yet exist precludes operational testing of their  
2820 adequacy or effectiveness as a necessary and sufficient set.

2821 That said, standards are critical to creating a SOA ecosystem where SOA services can be introduced,  
2822 used singularly, and combined with other services to deliver complex business functionality. As with other  
2823 aspects of SOA governance, the governance body should identify the minimum set felt to be needed and  
2824 rigorously enforce that that set be used where appropriate. The governance body takes care to expand  
2825 and evolve the mandated standards in a predictable manner and with sufficient technical guidance that  
2826 new services are able to coexist as much as possible with the old, and changes to standards do not  
2827 cause major disruptions.

2828 Another area that may see increasing activity as SOA expands is additional regulation by governments  
2829 and associated legal institutions. New laws may deal with transactions that are service based, possibly  
2830 including taxes on the transactions. Disclosure laws may mandate certain elements of description so both  
2831 the consumer and provider act in a predictable environment and are protected from ambiguity in intent or  
2832 action. Such laws spawn rules and regulations that will influence the metrics collected for evaluation of  
2833 compliance.

#### 2834 **5.1.3.4 Considerations for SOA Governance**

2835 The Reference Architecture definition of a loosely coupled system is one in which the constraints on the  
2836 interactions between components are minimal: sufficient to permit interoperation without additional  
2837 constraints that may be an artifact of implementation technology. While governance experience for  
2838 standalone systems provides useful guides, we must be careful not to apply constraints that would  
2839 preclude the flexibility, agility, and adaptability we expect to realize from a SOA ecosystem.

2840 One of the strengths of the SOA paradigm is it can make effective use of diversity rather than requiring  
2841 monolithic solutions. Heterogeneous organizations can interact without requiring each conforms to  
2842 uniform tools, representation, and processes. However, with this diversity comes the need to adequately  
2843 define those elements necessary for consistent interaction among systems and participants, such as  
2844 which communication protocol, what level of security, which vocabulary for payload content of messages.  
2845 The solution is not always to lock down these choices but to standardize alternatives and standardize the  
2846 representations through which an unambiguous identification of the alternative chosen can be conveyed.  
2847 For example, the URI standard specifies the URI string, including what protocol is being used, what is the  
2848 target of the message, and how parameters may be attached. It does not limit the available protocols, the  
2849 semantics of the target address, or the parameters that can be transferred. Thus, as with our definition of  
2850 loose coupling, it provides absolute constraints but minimizes which constraints it imposes.

2851 There is not a one-size-fits-all governance but a need to understand the types of things governance is  
2852 called upon to do in the context of the goals of the SOA paradigm. Some communities may initially desire  
2853 and require very stringent governance policies and procedures while others see need for very little. Over  
2854 time, best practices will evolve, resulting in some consensus on a sensible minimum and, except in  
2855 extreme cases where it is demonstrated to be necessary, a loosening of strict governance toward the  
2856 best practice mean.

2857 A question of how much governance may center on how much time governance activities require versus  
2858 how quickly is the system being governed expected to respond to changing conditions. For large single  
2859 systems that take years to develop, the governance process could move slowly without having a serious  
2860 negative impact. For example, if something takes two years to develop and the steps involved in  
2861 governance take two months to navigate, then the governance can go along in parallel and may not have  
2862 a significant impact on system response to changes. Situations where it takes as long to navigate  
2863 governance requirements as it does to develop a response are examples where governance may need to  
2864 be reevaluated as to whether it facilitates or inhibits the desired results. Thus, the speed at which services  
2865 are expected to appear and evolve must be considered when deciding the processes for control. The  
2866 added weight of governance should be appropriate for overall goals of the application domain and the  
2867 service environment.

2868 Governance, as with other aspects of any SOA implementation, should start small and be conceptualized  
2869 in a way that keeps it flexible, scalable, and realistic. A set of useful guidelines would include:

- 2870 • Do not hardwire things that will inevitably change. For example, develop a system that uses the  
2871 representation of policies rather than code the policies into the implementations.
- 2872 • Avoid setting up processes that demo well for three services without considering how they may  
2873 work for 300. Similarly, consider whether the display of status and activity for a small number of  
2874 services will also be effective for an operator in a crisis situation looking at dozens of services,  
2875 each with numerous, sometimes overlapping and sometimes differing activities.
- 2876 • Maintain consistency and realism. A service solution responding to a natural disaster cannot be  
2877 expected to complete a 6-week review cycle but be effective in a matter of hours.

## 2878 5.1.4 Architectural Implications of SOA Governance

2879 The description of SOA governance indicates numerous architectural requirements on the SOA  
2880 ecosystem:

- 2881 • Governance is expressed through policies and assumes multiple use of focused policy modules  
2882 that can be employed across many common circumstances. The following are thus **REQUIRED**:  
2883 ○ descriptions to enable the policy modules to be visible, where the description **SHOULD**  
2884 include a unique identifier for the policy as well as a sufficient, and preferably machine  
2885 process-able, representation of the meaning of terms used to describe the policy, its  
2886 functions, and its effects;  
2887 ○ one or more discovery mechanisms that enable searching for policies that best meet the  
2888 search criteria specified by a participant; where the discovery mechanism will have  
2889 access to the individual policy descriptions, possibly through some repository  
2890 mechanism;  
2891 ○ accessible storage of policies and policy descriptions, so participants can access,  
2892 examine, and use the policies as defined.
- 2893 • Governance requires that the participants understand the intent of governance, the structures  
2894 created to define and implement governance, and the processes to be followed to make  
2895 governance operational. This **REQUIRES**:  
2896 ○ an information collection site, such as a Web page or portal, where governance  
2897 information is stored and from which the information is always available for access;  
2898 ○ a mechanism to inform participants of significant governance events, such as changes in  
2899 policies, rules, or regulations;  
2900 ○ accessible storage of the specifics of Governance Processes;  
2901 ○ SOA services to access automated implementations of the Governance Processes
- 2902 • Governance policies are made operational through rules and regulations. This **REQUIRES**:  
2903 ○ descriptions to enable the rules and regulations to be visible, where the description  
2904 **SHOULD** include a unique identifier and a sufficient, and preferably a machine process-  
2905 able, representation of the meaning of terms used to describe the rules and regulations;  
2906 ○ one or more discovery mechanisms that enable searching for rules and regulations that  
2907 may apply to situations corresponding to the search criteria specified by a participant;  
2908 where the discovery mechanism will have access to the individual descriptions of rules  
2909 and regulations, possibly through some repository mechanism;  
2910 ○ accessible storage of rules and regulations and their respective descriptions, so  
2911 participants can understand and prepare for compliance, as defined.  
2912 ○ SOA services to access automated implementations of the Governance Processes.
- 2913 • Governance implies management to define and enforce rules and regulations. Management is  
2914 discussed more specifically in section 5.3, but in a parallel to governance, management  
2915 **REQUIRES**:  
2916 ○ an information collection site, such as a Web page or portal, where management  
2917 information is stored and from which the information is always available for access;  
2918 ○ a mechanism to inform participants of significant management events, such as changes  
2919 in rules or regulations;  
2920 ○ accessible storage of the specifics of processes followed by management.
- 2921 • Governance relies on metrics to define and measure compliance. This **REQUIRES**:  
2922 ○ the infrastructure monitoring and reporting information on SOA resources;  
2923 ○ possible interface requirements to make accessible metrics information generated or  
2924 most easily accessed by the service itself.

## 2925 5.2 Security Model

2926 Security is one aspect of confidence – the confidence in the integrity, reliability, and confidentiality of the  
2927 system. In particular, security in a SOA ecosystem focuses on those aspects of assurance that involve  
2928 the accidental or malicious intent of other people to damage, compromise trust, or hinder the availability  
2929 of SOA-based systems to perform desired capability.

## 2930 Security

2931 The set of mechanisms for ensuring and enhancing **trust** and confidence in the **SOA ecosystem**.

2932 Although many of the same principles apply equally to SOA as they do to other systems, implementing  
2933 security for a SOA ecosystem is somewhat different than for other contexts. The distributed nature of  
2934 SOA brings challenges related to the protection of resources against inappropriate access, and because  
2935 SOA embraces the crossing of ownership boundaries, the security issues associated with the movement  
2936 of data and access to functionality become more apparent in a SOA ecosystem.

2937 From a people perspective, Any comprehensive security solution for a SOA-based system must take into  
2938 account that people are effectively managing, maintaining, and utilizing the system appropriately. The  
2939 roles and responsibilities of the users, and the relationships between them must also be explicitly  
2940 understood and incorporated into a solution: any security assertions that may be associated with  
2941 particular interactions originate in the people that are behind the interaction.

2942 We analyze security in terms of the social structures that define the legitimate permissions, obligations  
2943 and roles of people in relation to the system, and mechanisms that must be put into place to realize a  
2944 secure system. The former are typically captured in a series of security policy statements; the latter in  
2945 terms of security guards that ensure that policies are enforced.

2946 How and when to apply these derived security policy mechanisms is directly associated with the  
2947 assessment of the *threat model* and a *security response model*. The threat model identifies the kinds of  
2948 threats that directly impact the messages, services, and/or the application of constraints. The response  
2949 model is the proposed mitigation to those threats. Properly implemented, the result can be an acceptable  
2950 level of risk to the safety and integrity within the SOA ecosystem.

## 2951 5.2.1 Secure Interaction Concepts

2952 We can characterize secure interactions in terms of key security concepts **[ISO/IEC 27002]**:  
2953 confidentiality, integrity, authentication, authorization, non-repudiation, and availability. The concepts for  
2954 secure interactions are well -defined in several other standards and publications. The security concepts  
2955 are therefore not explicitly defined here, but are discussed related to the SOA ecosystem perspective of  
2956 the SOA-RAF.

2957 Related to the security goals in this section, there may be significant security policy differences between  
2958 participants in different ownership domains. It is therefore important that these security policies and  
2959 security parameters are negotiated at the start of the relationship between systems of differing ownership  
2960 domains, and also when policies change between these domains. As with other policy conflicts, this is not  
2961 to say that every policy negotiation is a custom, point-to-point interaction. Rather, common mechanisms  
2962 and policies should be well known and appropriately accessible so the negotiation can be efficient and  
2963 lead to predictable conclusions. Unnecessary complexity does not lead to effective security.

### 2964 5.2.1.1 Confidentiality

2965 Confidentiality is concerned with the protection of privacy of participants in their interactions.  
2966 Confidentiality refers to the assurance that unauthorized entities are not able to read messages or parts  
2967 of messages that are transmitted, and is typically implemented by using encryption. Confidentiality has  
2968 degrees: in a completely confidential exchange, third parties would not even be aware that a confidential  
2969 exchange has occurred. In some cases, the identities of the participants may be known but the content of  
2970 the exchange obscured. In other cases, only portions of sensitive data in the exchange are encrypted.

2971 Different ownership domains may have policies related to encryption mechanisms between consumers  
2972 and providers, and such policies need to be negotiated and understood prior to any interaction.

### 2973 5.2.1.2 Integrity

2974 Integrity refers to the assurance that information has not been altered in transit, and is concerned with the  
2975 protection of information that is exchanged – either from inadvertent or intentional corruption. Section  
2976 5.2.4 describes common computing techniques for providing both confidentiality and integrity during  
2977 message exchanges.

2978 **5.2.1.3 Authentication**

2979 Authentication is concerned with adequately identifying actors in a potential interaction or joint action.  
2980 Various mechanisms and protocols can be used to achieve this goal. A combination of **identifiers** (as  
2981 discussed in section 3.2.4.1) and other attributes of an actor is typically used to achieve this. The set of  
2982 attribute values that claim to identify a specific actor are matched against the set of reference values  
2983 expected for that actor and that are maintained by some trusted authority. If the comparison results in a  
2984 sufficient match, authentication has been achieved. Which specific set of attributes is considered an  
2985 adequate basis for comparison will be context-dependent and specifying such sets is not within the scope  
2986 of the SOA-RAF.

2987 In addition to the concern of adequately identifying each actor involved in the interaction, there may also  
2988 be a need to provide authentication information related to the subject that initiated an interaction involving  
2989 the combination of intermediary actors in a service orchestration scenario. In such a case, consumers  
2990 and services work *on behalf of* the initiator of the interaction, and there may need to be mechanisms in  
2991 place to identify the interaction initiator. This concern is covered later in section 5.2.5.

2992 Authentication merely provides an assertion that an actor is the person or agent that it claims to be. Of  
2993 itself, it does not provide a 'green light' to proceed with the interaction – this is rather the concern of  
2994 **authorization**, covered below.

2995 **5.2.1.4 Authorization**

2996 Authorization concerns the legitimacy of the interaction, providing assurance that the actors have  
2997 permission to participate in the interaction. Authorization refers to the means by which a stakeholder may  
2998 be assured that the information and actions that are exchanged are either explicitly or implicitly approved.

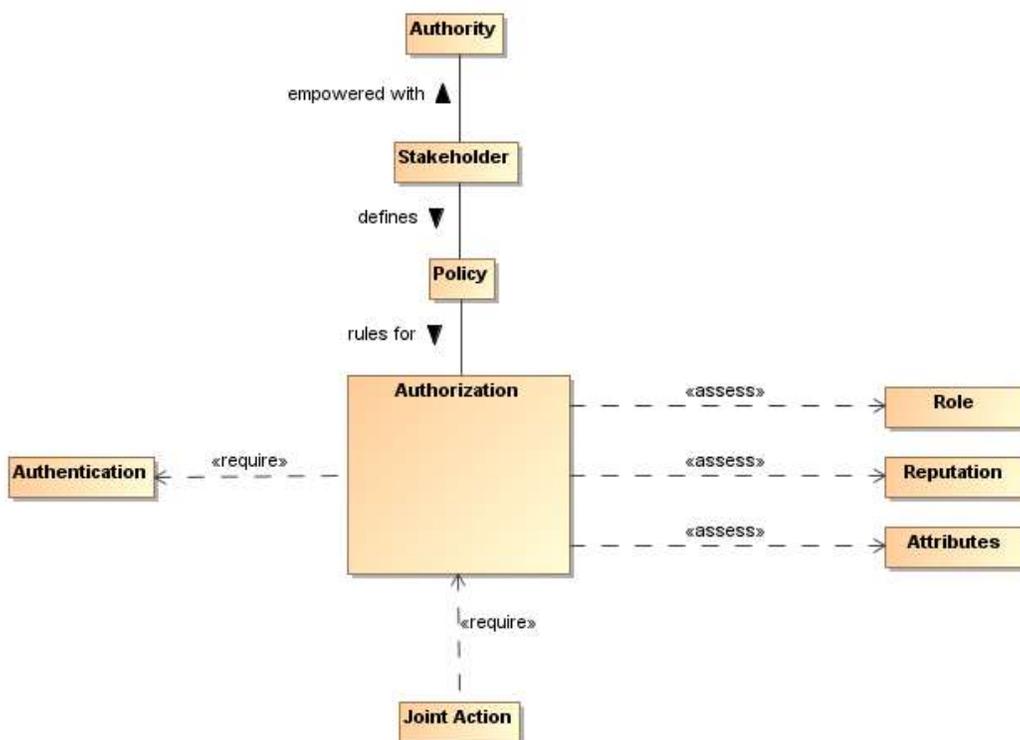

Figure 41 - Authorization

2999  
3000 The role of access control policy for security is to permit stakeholders to express their choices. In *Figure*  
3001 *41*, such a policy is a written constraint and the role, reputation, and attribute assertions of actors are  
3002 evaluated according to the constraints in the authorization policy. A combination of security mechanisms  
3003 and their control via explicit policies can form the basis of an authorization solution.

3005 The roles and attributes which provide a participant's credentials are expanded to include reputation.  
3006 Reputation often helps determine willingness to interact; for example, reviews of a service provider will

3007 influence the decision to interact with the service provider. The roles, reputation, and attributes are  
3008 represented as assertions measured by authorization decision points.

### 3009 **5.2.1.5 Non-repudiation**

3010 Non-repudiation concerns the accountability of participants. To foster trust in the performance of a system  
3011 used to conduct shared activities, it is important that the participants are not able to later deny their  
3012 actions: to repudiate them. Non-repudiation refers to the means by which a participant may not, at a later  
3013 time, successfully deny having participated in the interaction or having performed the actions as reported  
3014 by other participants.

### 3015 **5.2.1.6 Availability**

3016 Availability concerns the ability of systems to use and offer the services for which they were designed. An  
3017 example of threats against availability is a Denial Of Service (DoS) attack in which attackers attempt to  
3018 prevent legitimate access to service or set of services by flooding them with bogus requests. As  
3019 functionality is distributed into services in a SOA ecosystem, availability protection is paramount.

## 3020 **5.2.2 Where SOA Security is Different**

3021 The distributed nature of the SOA ecosystem brings challenges related to the protection of resources  
3022 against inappropriate access, and because the SOA paradigm embraces the crossing of ownership  
3023 boundaries, providing security in such an environment provides unique challenges. The evolution of  
3024 sharing information within a SOA ecosystem requires the flexibility to dynamically secure computing  
3025 interactions where the owning social groups, roles, and authority are constantly changing as described in  
3026 section 5.1.3.1.

3027 Standards for security, as is the case with all aspects of SOA implementation and use, play a large role in  
3028 flexible security on a global scale. SOA security may also involve greater auditing and reporting to adhere  
3029 to regulatory compliance established by governance structures.

## 3030 **5.2.3 Security Threats**

3031 There are a number of ways in which an attacker may attempt to compromise the security within a SOA  
3032 ecosystem, primarily as attacks on the security concerns listed in section 5.2.1. The two primary sources  
3033 of attack are (1) third parties attempting to subvert interactions between legitimate participants; and (2)  
3034 entities that are participating but attempting to subvert other participants.

3035 In a SOA ecosystem where there may be multiple ownership boundaries and trust boundaries, it is  
3036 important to understand these threats and protections that must be effective. Each technology choice in  
3037 the realization of a SOA-based system can potentially have many threats to consider. Although these  
3038 threats are not unique to SOA and can be mitigated by applying cryptographic techniques (digital  
3039 signatures, encryption, and various cryptographic protocols) and security technologies, it is important that  
3040 such threats are understood in order to provide solutions for thwarting such attacks and minimizing risk.

### 3041 **5.2.3.1 Message alteration**

3042 If an attacker is able to modify the content (or even the order) of messages that are exchanged without  
3043 the legitimate participants being aware of it then the attacker has successfully compromised the security  
3044 of the system. In effect, the participants may unwittingly serve the needs of the attacker rather than their  
3045 own. Cryptographic mechanisms (hash codes, digital signatures, and cryptographic protocols) can be  
3046 used as a protection mechanism against alteration.

### 3047 **5.2.3.2 Message interception**

3048 If an attacker is able to intercept and understand messages exchanged between participants, then the  
3049 attacker may be able to gain advantage. Cryptographic protocols can be used as a protection against  
3050 interception.

3051 **5.2.3.3 Man in the middle**

3052 In a man-in-the-middle attack, the legitimate participants believe that they are interacting with each other;  
3053 but are in fact interacting with an attacker. The attacker attempts to convince each participant that he is  
3054 their correspondent; whereas in fact he is not.

3055 In a successful man-in-the-middle attack, legitimate participants do not have an accurate understanding  
3056 of the state of the other participants. The attacker can use this to subvert the intentions of the participants.

3057 **5.2.3.4 Spoofing**

3058 In a spoofing attack, the attacker convinces a participant that he is another party.

3059 **5.2.3.5 Denial of service attack**

3060 A Denial of Service (DoS) attack is an attack on the availability and performance of a service or set of  
3061 services. In a DoS attack, the attacker attempts to prevent legitimate users from making use of the  
3062 service. A DoS attack is easy to mount and can cause considerable harm by preventing legitimate  
3063 interactions in a SOA ecosystem, or by slowing them down enough, the attacker may be able to  
3064 simultaneously prevent legitimate access to a service and to attack the service by another means. One of  
3065 the features of a DoS attack is that it does not require valid interactions to be effective: responding to  
3066 invalid messages also takes resources and that may be sufficient to cripple the target. A variation of the  
3067 DoS attack is the Distributed Denial of Service (DDoS) attack, where an attacker uses multiple agents to  
3068 the attack the target.

3069 **5.2.3.6 Replay attack**

3070 In a replay attack, the attacker captures the message traffic during a legitimate interaction and then  
3071 replays part of it to the target. The target is persuaded that an interaction similar to the previous one is  
3072 being repeated and it responds as though it were a legitimate interaction.

3073 **5.2.3.7 False repudiation**

3074 In false repudiation, a user completes a normal interaction and then later attempts to deny that the  
3075 interaction occurred.

3076 **5.2.4 Security Responses**

3077 Security goals are never absolute: it is not possible to guarantee 100% confidentiality, non-repudiation,  
3078 etc. However, a well-designed and implemented security response model can reduce security risk to  
3079 acceptable levels. For example, using a well-designed cipher to encrypt messages may make the cost of  
3080 breaking communications so great and so lengthy that the information obtained is valueless.

3081 Performing threat assessments, devising mitigation strategies, and determining acceptable levels of risk  
3082 are the foundation for an effective process to mitigating threats in a cost-effective way.<sup>10</sup> Architectural

---

<sup>10</sup> In practice, there are perceptions of security from all participants regardless of ownership boundaries. Satisfying security policy often requires asserting sensitive information about the message initiator. The perceptions of this participant about information privacy may be more important than actual security enforcement within the SOA ecosystem for this stakeholder.

3083 choices, as well as choices in hardware and software to realize a SOA implementation will be used as the  
3084 basis for threat assessments and mitigation strategies.

#### 3085 **5.2.4.1 Privacy Enforcement**

3086 The most efficient mechanism to assure confidentiality is the encryption of information. Encryption is  
3087 particularly important when messages must cross trust boundaries; especially over the Internet. Note that  
3088 encryption need not be limited to the content of messages: it is possible to obscure even the existence of  
3089 messages themselves through encryption and 'white noise' generation in the communications channel.

3090 The specifics of encryption are beyond the scope of this Reference Architecture Framework. However, we  
3091 are concerned about how the connection between privacy-related policies and their enforcement is made.

3092 Service contracts may express confidentiality security policies and the cryptographic mechanisms  
3093 required (e.g. ciphers, cryptographic protocols). Between ownership boundaries, there may also be  
3094 similar security policies that define requirements for privacy between them. Between such boundaries,  
3095 there may be a Policy Enforcement Point (PEP) for enforcing such requirements which may, for example,  
3096 automatically encrypt messages as they leave a trust boundary; or perhaps simply ensuring that such  
3097 messages are suitably encrypted in such a way as to comply with the policy.

#### 3098 **5.2.4.2 Integrity Protection**

3099 To protect against message tampering or inadvertent message alteration, messages may be  
3100 accompanied by the digital signature of the hash code of a message. Any alteration of the message or  
3101 signature would result in a failed signature validation, indicating an integrity compromise. Digital  
3102 signatures therefore provide a mechanism for integrity protection.

3103 A digital signature also provides non-repudiation, which is an assurance of proof that a subject signed a  
3104 message. Utilizing a digital signature algorithm based on public key cryptography, a digital signature  
3105 cryptographically binds the signer of the message to its contents, ensuring that the signer cannot  
3106 successfully deny sending the message.

3107 The use of a Public Key Infrastructure (PKI) provides the support and infrastructure for digital signature  
3108 capabilities, and there may also be security policies related to digital signatures between organizational  
3109 boundaries, as well as trust relationships between multiple Certificate Authorities (CAs) across the  
3110 boundaries.

#### 3111 **5.2.4.3 Message Replay Protection**

3112 To protect against replay attacks, messages may also contain information that can be used to detect  
3113 replayed messages. A common approach involves the use of a message ID, a timestamp, and the  
3114 message's intended destination, signed along with the message itself. A message recipient may be able  
3115 to thwart a message replay attack by

- 3116 • checking to ensure that it has previously not processed the message ID
- 3117 • validating that the timestamp is within a certain time threshold to ensure message freshness
- 3118 • ensuring that the recipient is indeed the intended destination
- 3119 • validating the digital signature, which provides non-repudiation of the message sender and  
3120 checks the integrity of the message ID, timestamp, the destination, and the message itself,  
3121 proving that none of the information was altered

3122 Cryptographic protocols between participants can also be used to thwart replay attacks.

#### 3123 **5.2.4.4 Auditing and Logging**

3124 False repudiation involves a participant denying that it authorized a previous interaction. In addition to the  
3125 use of digital signatures, an effective strategy for responding to such a denial involves logging of  
3126 interactions and the ability to audit the resulting logs. The more detailed and comprehensive an audit trail  
3127 is, the less likely it is that a false repudiation would be successful.

3128 Given the distributed nature of the SOA ecosystem, one challenge revolves around the location of the  
3129 audit logs of services. It would be very difficult, for example, to do cross-log analysis of services that write  
3130 logs to their own file system. For this reason, a common approach revolves around the use of auditing  
3131 services, where services may stream auditing information to a common auditing component which can  
3132 then be used to provide interaction analysis and a common view.

#### 3133 **5.2.4.5 Graduated engagement**

3134 Although many DoS attacks can typically be thwarted by intrusion detection systems, they are sometimes  
3135 difficult to detect because requests to services seem to be legitimate. It is therefore prudent to be careful  
3136 in the use of resources when responding to requests. If a known consumer tries to interact via a public  
3137 interface that is not specified in the service contract, a service is not obliged to notice such an interaction  
3138 request. In order to avoid vulnerability to DoS attacks, a service provider should be careful not to commit  
3139 resources beyond those implied by the current state of interactions; this permits a graduation in  
3140 commitment by the service provider that mirrors any commitment on the part of service consumers and  
3141 attackers alike. A successful approach, however, cannot be implemented at the service-level alone – it  
3142 involves a defense-in-depth strategy, coupling the use of intrusion detection systems, routers, firewalls,  
3143 and providing the protections discussed in this section.

### 3144 **5.2.5 Access Control**

#### 3145 **5.2.5.1 Conveying Authentication and Authorization Information**

3146 When an actor initiates an interaction with a service, that service may call other services or be part of a  
3147 chain of service interactions as it carries out its functionality. Any service provider is aware of the  
3148 immediate service consumer but, in some cases, for example, to provide proper access control to its data,  
3149 a service provider may want information on who besides the immediate consumer is expected to see the  
3150 data that is being requested. A significant question is whether trust of the immediate consumer should  
3151 include trust that the immediate consumer will ensure proper data handling by its immediate consumer  
3152 and back through any chain of service interactions. If this is not sufficient, conveying authentication and  
3153 authorization information becomes a necessity, and the challenge becomes one of creating a conveyance  
3154 process that gives more assurance than merely trust of the immediate consumer. This is a challenge both  
3155 within and between ownership domains.

3156 The security concerns related to conveying authentication and authorization information throughout  
3157 intermediaries introduce significant complexity. Although an actor may directly authenticate to a service  
3158 provider, that service provider may interact with other service providers in order to carry out its  
3159 functionality, possibly without the knowledge of the initiator. There may therefore be privacy and  
3160 confidentiality concerns related to conveying security information about the initiating actor. There may  
3161 also be issues related to authorization, in that the initiating actor may need to explicitly delegate consent  
3162 for intermediate services to act on the initiator's behalf.

3163 The following sections cover two approaches for conveying authentication and authorization information  
3164 in a SOA ecosystem. These approaches involves conveying sufficient attributes, as discussed in section  
3165 5.2.1.3, which may be a single unique identifier or a set of identifiers that can be used in access control  
3166 decisions.

3167 In the first approach, the service consumer creates and passes an assertion about the initiating actor. In  
3168 the second approach, a service is trusted to issue assertions about subjects. Each has specific  
3169 implications for a SOA ecosystem.

#### 3170 **5.2.5.1.1 Sender-Vouches Approaches**

3171 In a “sender vouches” approach, a service consumer creates an assertion, *vouching* for certain security  
3172 information about the initiator of the interaction, and possible about other actors in a series (chain) of  
3173 service interactions. This assertion contains sufficient attributes that can be used in access control  
3174 decisions, and is sent, or propagated, to the service provider. Trust of such an assertion is therefore  
3175 based on the provider's trust of the consumer, and also there needs to be an understanding of such

3176 assertions between ownership boundaries. In a SOA ecosystem, such trust must be established at the  
3177 beginning of each relationship.

3178 When such assertions are reused in service orchestration scenarios beyond the initial consumer-provider  
3179 interaction, there can be significant security risks<sup>11</sup>.

- 3180 • *Trust of Message Senders*. Because the trust of the assertion is based on the trust of the  
3181 message senders, the more intermediaries there are, trust can degrade as the distance between  
3182 the initiator and the service being called becomes greater. Trust may, therefore, be dependent on  
3183 the trust of every sender in the chain to properly pass the claim.
- 3184 • *Risk of Vulnerabilities in Intermediaries*. Because the trust of the assertion relies on the trust of  
3185 each participant in the interaction, a risk is that intermediary services may become compromised  
3186 and may inaccurately send false claims. Depending on the exact messaging syntax, an  
3187 intermediary service could potentially manipulate the assertion or substitute another assertion.  
3188 There could also be impersonation of the intermediary services, affecting the reliability of the  
3189 interaction.

3190 Approaches for mitigating risks in sender-vouches approaches involve a careful combination of SOA  
3191 security governance, limiting the re-use of assertions beyond a certain number of points, establishing  
3192 conditions of use for propagated assertions, keeping track of the history of the assertion in the interaction,  
3193 and the use of digital signatures by an asserting party.

3194 Between ownership domains, such an approach is even more challenging, as different ownership  
3195 domains may recognize different authentication authorities and may not recognize identities from other  
3196 organizations. Security policies that relate to the conveying of security information across boundaries  
3197 must occur at the start of the relationship, with many solutions involving reciprocity of trust between  
3198 authentication and authorization authorities from each domain.

#### 3199 **5.2.5.1.2 Token Service-based Approaches**

3200 This approach revolves around use of a *token service* or a set of token services trusted to vouch for  
3201 security information about authenticated actors in the interaction. In this approach, a token service issues  
3202 a token which is an assertion that contains sufficient attributes that can be used in access control  
3203 decisions. The service consumer passes this token, along with a request, to a service provider.

3204 After the original consumer passes the issued token to the service, the recipient service later acting as a  
3205 consumer may then choose to propagate the token to other service providers. Much like the risks  
3206 associated with the reuse of assertions in sender-vouches approaches, there are risks associated with  
3207 the reuse of tokens issued by the token service beyond the initial consumer-provider interaction. Most  
3208 token service protocols and specifications, therefore, provide the capability for “refreshing” tokens for  
3209 reuse in such situations. In this case, each actor retrieving a token may request that the token service  
3210 issue a “refresh token” that can be propagated for a subsequent service interaction. Utilizing refresh  
3211 tokens removes the risks associated with reuse.

3212 This approach differs from the sender-vouches model in that trust of the token is not based on the  
3213 message sender, but is based on the trust of the token service that issued it. In interactions between  
3214 ownership domains, the establishment of the trust of the token services must be agreed to at the start of  
3215 the relationship, and there must be an understanding of the policies associated with processing the  
3216 tokens. To facilitate this, token services in one domain can often be used to “translate” tokens from other  
3217 domains, issuing new tokens that are understood by services and consumers in its domain.

---

<sup>11</sup> Such risks and others are documented in [SMITH]

3218 Unlike sender-vouches approaches, the token service approach revolves around a trusted token service  
3219 or a set of trusted token services, and there may be architectural implications related to performance and  
3220 availability. It is therefore advised that solutions that provide elastic scalability be used to ensure that  
3221 token services are readily available to respond to requests.

## 3222 **5.2.5.2 Access Control Approaches**

3223 Access control revolves around security policy. If access control policy can be discovered and processed,  
3224 and if authorization credentials of actors can be retrieved, access control can be successfully enforced.  
3225 Architectural flexibility for authorization is achieved by logically separating duties into Policy Decision  
3226 Points (PDPs) and Policy Enforcement Points (PEPs). A PDP is the point at which access control  
3227 decisions are made, based on an expressed access control policy and an actor's authorization  
3228 credentials. The enforcement of the decision is delegated to a PEP. Some standards, such as XACML  
3229 (the eXtensible Access Control Markup Language), decompose the policy model further into Policy  
3230 Administration Points (PAPs) that create policy and the Policy Information Points (PIPs) that query  
3231 attributes for actors requesting access to resources. There are many strategies for how PDPs and PEPs  
3232 can work together, each with architectural implications that have an impact on security, performance, and  
3233 scalability.

3234 As access control policy may vary between ownership domains, the negotiation of access control policies  
3235 between such domains must occur at the start of the relationship, regardless of the underlying  
3236 architectural approaches.

3237 Different security services implementations may dictate different architectural approaches and have  
3238 different implications. This section provides a brief overview of such approaches.

### 3239 **5.2.5.2.1 Centralized Access Control Approaches**

3240 A centralized approach uses a policy server (or a set of policy servers) to act as a PDP, and utilizes the  
3241 current access control policy to make an access control decision for an actor requesting access to a  
3242 resource. A positive aspect of this approach can be information hiding because services may not need to  
3243 know the authorization credentials of the actor or the specific policy being enforced. The centralized  
3244 model protects that information in cases where this information may be sensitive or confidential. Another  
3245 positive aspect of this approach is that the policy services can provide access control decisions  
3246 consistently, and any change to access control policy can be changed in one place.

3247 However, negative aspects of this model are those common with any type of centralized architecture,  
3248 including performance and availability. Given performance, availability, and scalability concerns, any  
3249 centralized solution should be coupled with alternative approaches for greater flexibility.

### 3250 **5.2.5.2.2 Decentralized Access Control Approaches**

3251 In a decentralized approach, the service consumer propagates a token related to its identity (and possibly  
3252 other identities in a service chain), and this is assessed by a "local" PDP and PEP. The service PDP  
3253 refers to locally expressed policy, and therefore, its PDP can inspect the policy and the security  
3254 credentials propagated in order to make an access control decision. If only identity information about the  
3255 initiator is propagated into the service, the service may retrieve additional authorization credentials from  
3256 an Attribute Service lookup based on the identity.

3257 The decentralized model alleviates the performance concerns of the purely central model, as it does not  
3258 require access to a set of centralized servers used to make access control decisions. Because the policy  
3259 is locally expressed, the service may enforce its own policy, expressed in its service contract with service  
3260 consumers.

3261 There are two potential concerns with this model. One concern is that there is no information hiding. If an  
3262 assertion about the initiator is propagated into the service, the service may need security credentials of  
3263 the consumer in order to execute access control policy, and these credentials may be sensitive or  
3264 confidential. A second concern revolves around access control policy management. As this decentralized  
3265 model is based on making "local" (not centralized) access control decisions at the service level, there is a  
3266 possibility that

- 3267 • Access control policies may not be consistently enforced throughout the SOA ecosystem

- 3268 • Changing organizational access control policies require policy changes throughout the SOA  
3269 ecosystem (vs. in a central location) and may be therefore difficult to immediately enforce.  
3270 Therefore, there is a danger that access control policies may be out-of-date and inconsistent.  
3271 It is therefore prudent that in using such an approach, that these concerns be addressed.

### 3272 5.2.5.2.3 Hybrid Access Control Approaches

3273 A purely centralized approach has significant weaknesses related to performance, availability, and  
3274 scalability; a purely decentralized approach does not support a requirement to have centralized control of  
3275 access control policy. In response, hybrid approaches have emerged to provide a “happy medium”  
3276 between local control of policy (where services express all policy) and central control of policy (where a  
3277 central policy server expresses all policy). In hybrid models, each service can both express local policy  
3278 and leverage global organizational policy (which can be periodically downloaded or syndicated to the  
3279 local services) in order to make decisions. The balance between the models will depend on the context in  
3280 which the hybrid is applied.

## 3281 5.2.6 Architectural Implications of SOA Security

3282 Providing SOA security in an ecosystem of governed services has the following implications on the policy  
3283 support and the distributed nature of mechanisms used to assure SOA security:

- 3284 • Security expressed through security messaging policies **SHOULD** follow the same architectural  
3285 implications as described in Section 4.4.3 for policies and contracts architectural implications.
- 3286 • Security policies **MUST** have mechanisms to support security description administration, storage,  
3287 and distribution.
- 3288 • Service descriptions **SHOULD** include a sufficiently rich meta-structure to unambiguously indicate  
3289 which security policies are required and where policy options are possible.
- 3290 • The mechanisms that make-up the execution context in secure SOA-based systems **SHOULD**:  
3291 ○ provide protection of the confidentiality and integrity of message exchanges;  
3292 ○ be distributed so as to provide available policy-based identification, authentication, and  
3293 authorization;  
3294 ○ ensure service availability to consumers;  
3295 ○ be able to scale to support security for a growing ecosystem of services;  
3296 ○ be able to support security between different communication means or channels;  
3297 ○ have a framework for resolving conflicts between security policies.
- 3298 • Common security services **SHOULD** include the ability for:  
3299 ○ authentication and establishing/validating credentials  
3300 ○ retrieval of authorization credentials (attribute services);  
3301 ○ enforcing access control policies;  
3302 ○ intrusion detection and prevention;  
3303 ○ auditing and logging interactions and security violations.

## 3304 5.3 Management Model

### 3305 5.3.1 Management

3306 Management is a process of controlling resources in accordance with the policies and principles defined  
3307 by Governance.

3308 There are three separate but linked domains of interest within the management of a SOA ecosystem:

- 3309 1. the management and support of the resources that are involved in any complex structures – of  
3310 which SOA ecosystems are excellent examples;
- 3311 2. the promulgation and enforcement of the policies and service contracts agreed to by the  
3312 stakeholders in the SOA ecosystem;
- 3313 3. the management of the relationships of the participants – both to each other and to the services  
3314 that they use and offer.

3315 There are many artifacts related to management. Historically, systems management capabilities have  
3316 been organized by the FCAPS functions (based on ITU-T Rec. M.3400 (02/2000), *TMN Management*  
3317 *Functions*):

- 3318 • fault management,
- 3319 • configuration management,
- 3320 • account management,
- 3321 • performance and security management.

3322 The primary task of the functional groups is to concentrate on maintaining systems in a trusted, active,  
3323 and accessible state.

3324 In the context of the SOA ecosystem, we see many possible resources that may require management  
3325 such as services, service descriptions, service contracts, policies, roles, relationships, security, people  
3326 and systems that implement services and infrastructure elements. In addition, given the ecosystem  
3327 nature, it is also potentially necessary to manage the business relationships between participants.

3328 Successful operation of a SOA ecosystem requires trust among the stakeholders and between them and  
3329 the SOA-based system elements. In contrast, regular systems in technology are not necessarily operated  
3330 or used in an environment requiring trust before the stakeholders make use of the system. Indeed, many  
3331 of these systems exist in hierarchical management structures, within which use may be mandated by  
3332 legal requirement, executive decision, or good business practice in furthering the business' strategy. The  
3333 pre-condition of trust in the SOA ecosystem is rooted both in the principles of service orientation and in  
3334 the distributed, authoritative ownership of independent services. Even for hierarchical management  
3335 structures applied to a SOA ecosystem, the service in use should have a contractual basis rather than  
3336 solely being mandated.

3337 Trust may be established through agreements/contracts, policies, or implicitly through observation of  
3338 repeated interactions with others. Explicit trust is usually accompanied by formalized documents suitable  
3339 for management. Implicit trust adds fragility to the management of a SOA ecosystem because failure to  
3340 maintain consistent and predictable interactions will undermine the trust between participants and within  
3341 the ecosystem as a whole.

3342 Management in a SOA ecosystem is thus concerned with management taking actions that will establish  
3343 the condition of trust that must be present before engaging in service interactions. These concerns should  
3344 largely be handled within the governance of the ecosystem. The policies, agreements, and practices  
3345 defined through governance provide the boundaries within which management operates and for which  
3346 management must provide enforcement and feedback. However, governance alone cannot foresee all  
3347 circumstances but must offer sufficient guidance where agreement between all stakeholders cannot be  
3348 reached. Management in these cases must be flexible and adaptable to handle unanticipated conditions  
3349 without unnecessarily breaking trust relationships.

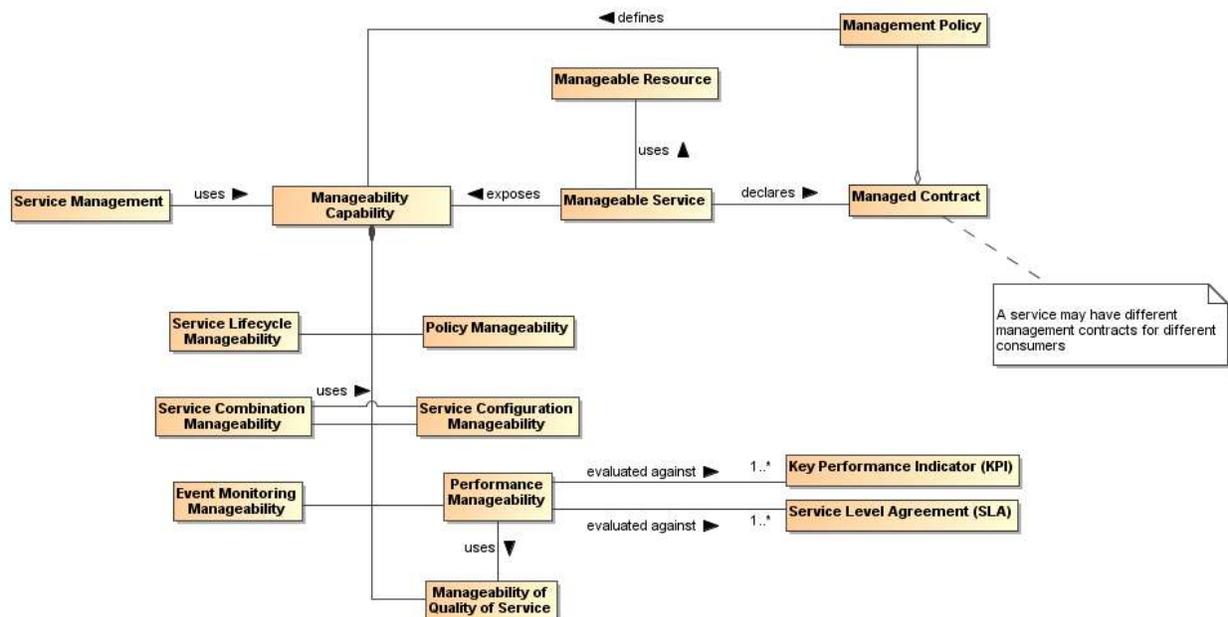

3350 Service management is the process – manual, automated, or a combination – of proactively monitoring  
3351 and controlling the behavior of a service or a set of services. Service management operates under  
3352 constraints attributed to the business and social context. Specific policies may be used to govern cross-  
3353 boundary relationships. Managing solutions based on such policies (and that may be used across  
3354 ownership boundaries) raises issues that are not typically present when managing a service within a  
3355 single ownership domain. Care is therefore required in managing a service when the owner of the  
3356 service, the provider of the service, the host of the service and mediators to the service may all belong to  
3357 different stakeholders.

3358 Cross-boundary service management takes place in, at least, the following situations:

- 3359 • using combinations of services that belong to different ownership domains
- 3360 • using of services that mediate between ownership domains
- 3361 • sharing monitoring and reporting means and results.

3362 These situations are particularly important in ecosystems that are highly decentralized, in which the  
3363 participants interact as peers as well as in the 'master-servant' mode.

3364 The management model shown in *Figure 42* conveys how the SOA paradigm applies to managing  
3365 services. Services management operates via service metadata, such as properties associated with  
3366 service lifecycles and with service use, which are typically collected in or accessed through the service  
3367 description.

3369

3370

Figure 42 - Management model in SOA ecosystem

3371 The service metadata of interest is that set of service properties that is manageable. These manageability  
 3372 properties are generally identifiable for any service consumed or supplied within the ecosystem. The  
 3373 necessary existence of these properties within the SOA ecosystem motivates the following definitions:

### 3374 **Manageability**

3375 A capability that allows a **resource** to be controlled, monitored, and reported on with respect to  
 3376 some properties.

### 3377 **Manageability property**

3378 A property used in the **manageability** of a **resource**. The fundamental unit of management in  
 3379 systems management.

3380 Note that manageability is not necessarily a part of the managed entities themselves and are generally  
 3381 considered to be external to the managed entities.

3382 Each resource may be managed through a number of aspects of management, and the resources may  
 3383 be grouped based on similar aspects. For example, resources may be grouped according to the aspect  
 3384 referred to as 'Configuration Manageability' for the collection of services. Some resources may not be  
 3385 managed under a particular capability if there are no manageability aspects with a clear meaning or use.  
 3386 As an example, all resources within a SOA ecosystem have a lifecycle that is meaningful within the  
 3387 ecosystem. Thus, all resources are manageable under Lifecycle Manageability. In contrast, not all  
 3388 resources report or handle events. Thus, Event Manageability is only concerned with those resources for  
 3389 which events are meaningful.

3390 **Life-cycle Manageability** of a service typically refers to how the service is created, how it is retired and  
 3391 how service versions must be managed. This manageability is a feature of the SOA ecosystem because  
 3392 the service cannot manage its own life cycle. Related properties may include the necessary state of the  
 3393 ecosystem for the creation and retirement of the service and the state of the ecosystem following the  
 3394 retirement of the service. The SOA ecosystem distinguishes between service composition and service  
 3395 aggregation: retiring of service composition leads to retiring of all services comprising the composition  
 3396 while retiring of service aggregation assumes that comprising services have their own life-cycle and can  
 3397 be used in another aggregation.

3398 Another important consideration is that services may have resource requirements, such as concurrent  
 3399 connectivity to a data source, which must be established at various points in the services' life cycles.

3400 However, actual providers of these resources may not be known at the time of the service creation and,  
3401 thus, have to be managed at service run-time.

3402 **Combination Manageability** of a service addresses management of service characteristics that allow for  
3403 creating and changing combinations in which the service participates or that the service combines itself.  
3404 Known models of such combinations are aggregations and compositions. Examples of patterns of  
3405 combinations are choreography and orchestration. In cases of business collaboration, combination of  
3406 services appears as cooperation of services. Combination Manageability drives implementation of the  
3407 Service Composability Principle of service orientation.

3408 Service combination manageability resonates with the methodology of process management.  
3409 Combination Manageability may be applied at different phases of service creation and execution and, in  
3410 some cases, can utilize Configuration Manageability.

3411 Service combinations typically contribute the most in delivering business values to the stakeholders.  
3412 Managing service combinations is the one of the most important tasks and features of the SOA  
3413 ecosystem.

3414 **Configuration Manageability** of a service allows managing the identity of and the interactions among  
3415 internal elements of the service, for example, a use of data encryption for internal inter-component  
3416 communication in particular deployment conditions. Also, Configuration Manageability correlates with the  
3417 management of service versions and configuration of the deployment of new services into the ecosystem.  
3418 Configuration Management differs from the Combination Manageability in the scope and scale of  
3419 manageability, and addresses lower level concerns than the architectural combination of services.

3420 **Event Monitoring Manageability** allows managing the categories of events of interest related to services  
3421 and reporting recognized events to the interested stakeholders. Such events may be the ones that trigger  
3422 service invocations as well as execution of particular functionality provided by the service. For example,  
3423 an execution of a set of financial market risk services, which implements choreography pattern, may be  
3424 started if certain financial event occurs in a stock exchange.

3425 Event Monitoring Manageability is a key lower-level manageability aspect, in which the service provider  
3426 and associated stakeholders are interested. Monitored events may be internal or external to the SOA  
3427 ecosystem. For example, a disaster in the oil industry, which is outside the SOA ecosystem of the Insurer,  
3428 can trigger the service's functionality that is responsible for immediate or constant monitoring of oil prices  
3429 in the oil trading exchanges and, respectively, modify the premium paid by the insured oil companies.

3430 **Performance Manageability** of a service allows controlling the service results, shared and sharable real  
3431 world effects against the business goals and objectives of the service. This manageability assumes  
3432 monitoring of the business performance as well as the management of this monitoring itself. Performance  
3433 Manageability includes business and technical performance manageability through a performance criteria  
3434 set, such as business key performance indicators (KPI) and service-level agreements (SLA).

3435 The performance business- and technical-level characteristics of the service should be known from the  
3436 service contract. The service provider and consumer must be able to monitor and measure these  
3437 characteristics or be informed about the results measured by a third party. An example of such monitoring  
3438 would be when the comparison of service performance results against an SLA is not satisfactory to the  
3439 consumer, and as a consequence, the consumer may replace the service by a service from a competitor.

3440 Performance Manageability is the instrument for providing compliance of the service with its service  
3441 contracts. Performance Manageability utilizes Manageability of Quality of Service.

3442 **Manageability of Quality of Service** deals with management of service non-functional characteristics  
3443 that may be of significant value to the service consumers and other stakeholders in the SOA ecosystem.  
3444 A classic example- of this is managing bandwidth offerings associated with a service.

3445 Manageability of quality of service assumes that the properties associated with service qualities are  
3446 monitored during the service execution. Results of monitoring may be compared against an SLA or a KPI,  
3447 which results in the continuous validation of how the service contract is preserved by the service provider.

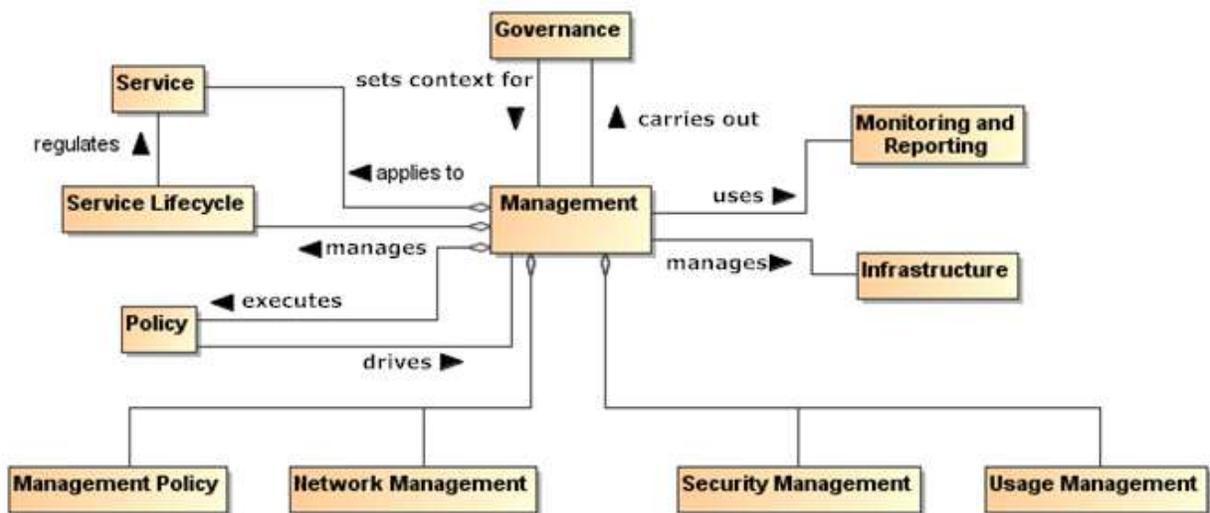

3448 **Policy Manageability** allows additions, changes and replacements of the policies associated with a  
3449 resource in the SOA ecosystem. The ability to manage those policies (such as promulgating policies,  
3450 retiring policies and ensuring that policy decision points and enforcement points are current) enables the  
3451 ecosystem to apply policies and *evaluate* the results.

3452 The ability to manage, i.e. use a particular manageability, requires policies from governance to be  
 3453 translated into detailed rules and regulations which are measured and monitored providing corresponding  
 3454 feedback for enforcement. At the same time, the execution of a management capability must adhere to  
 3455 certain policies governing the management itself. For example, a management has to enforce and control  
 3456 policies of compliance with particular industry regulation while the management is obliged by another  
 3457 policy to report on the compliance status periodically.

3458 Management of SOA ecosystem recognizes the manageability challenge and requires manageability  
 3459 properties to be considered for all aforementioned manageability cases. In the following subsections, we  
 3460 describe how these properties are used in the management as well as some relationships between  
 3461 management and other components of SOA ecosystem.

### 3462 5.3.2 Management Means and Relationships

3463 A minimal set of management issues for the SOA ecosystem is shown in *Figure 43* and elaborated in the  
 3464 following sections.

3465  
 3466 *Figure 43 - Management Means and Relationships in a SOA ecosystem*

#### 3467 5.3.2.1 Management Policy

3468 The management of resources within the SOA ecosystem may be governed by management policies. In  
 3469 a deployed SOA-based solution, it may well be that different aspects of the management of a given  
 3470 service are managed by different management services. For example, the life-cycle management of  
 3471 services often involves managing service versions. Managing quality of service is often very specific to  
 3472 the service itself; for example, quality of service attributes for a video streaming service are quite different  
 3473 to those for a banking system.

#### 3474 5.3.2.2 Network Management

3475 Network management deals with the maintenance and administration of large scale physical networks  
 3476 such as computer networks and telecommunication networks. Specifics of the networks may affect  
 3477 service interactions from performance and operational perspectives.

3478 Network and related system management execute a set of functions required for controlling, planning,  
 3479 deploying, coordinating, and monitoring the distributed services in the SOA ecosystem. However, while  
 3480 recognizing their importance, the specifics of systems management or network management are out of  
 3481 scope for this Reference Architecture Foundation.

#### 3482 5.3.2.3 Security Management

3483 Security Management includes identification of roles, permissions, access rights, and policy attributes  
 3484 defining security boundaries and events that may trigger a security response.

3485 Security management within a SOA ecosystem is essential to maintaining the trust relationships between  
3486 participants residing in different ownership domains. Security management must consider not just the  
3487 internal properties related to interactions between participants but ecosystem properties that preserve the  
3488 integrity of the ecosystem from external threats.

#### 3489 **5.3.2.4 Usage Management**

3490 Usage Management is concerned with how resources are used, including:

- 3491 • how the resource is accessed, who is using the resource, and the state of the resource (access  
3492 properties);
- 3493 • controlling or shaping demand for resources to optimize the overall operation of the ecosystem  
3494 (demand properties);
- 3495 • assigning costs to the use of resources and distributing those cost assignments to the  
3496 participants in an appropriate manner (financial properties).

3497

#### 3498 **5.3.3 Management and Governance**

3499 The primary role of governance in the context of a SOA ecosystem is to foster an atmosphere of  
3500 predictability, trust, and efficiency, and it accomplishes this by allowing the stakeholders to negotiate and  
3501 set the key policies that govern the running of the SOA-based solution. Recall that in an ecosystem  
3502 perspective, the goal of governance is less to have complete fine-grained control but more to enable the  
3503 individual participants to work together.

3504 Policies for a SOA ecosystem will tend to focus on the rules of engagement between participants; for  
3505 example, what kinds of interactions are permissible, how disputes are resolved, etc. While governance  
3506 may primarily focus on setting policies, management will focus on the realization and enforcement of  
3507 policies. Effective management in the SOA ecosystem requires an ability for governance to understand  
3508 the consequences of its policies, guidelines, and principles, and to adjust those as needed when  
3509 inconsistencies or ambiguity become evident from the operation of the management functions. This  
3510 understanding and adjustment must be facilitated by the results of management and so the mechanisms  
3511 for providing feedback from management into governance must exist.

3512 Governance operates via specialized activities and, thus, should be managed itself. Governance policies  
3513 are included in the Governance Framework and Processes, and driven by the enterprise business model,  
3514 business objectives and strategies. Where corporate management policies exist, these are usually guided  
3515 and directed by the corporate executives. In peer relationships, governance policies are set by either an  
3516 external entity and accepted by the peers or by the peers themselves. This creates the appropriate  
3517 authoritative level for the policies used for the management of the Governance Framework and  
3518 Processes. Management to operationalize governance controls the life-cycle of the governing policies,  
3519 including procedures and processes, for modifying the Governance Framework and Processes.

#### 3520 **5.3.4 Management and Contracts**

##### 3521 **5.3.4.1 Management for Contracts and Policies**

3522 As we noted above, management can often be viewed as the application of contracts and individual  
3523 policies to ensure the smooth running of the SOA ecosystem. Policies and service contracts specify the  
3524 service characteristics that have to be monitored, analyzed and managed. These also play an important  
3525 role as the guiding constraints for management, as well as being artifacts (e.g., policy and contractual  
3526 documents) that also need to be managed.

##### 3527 **5.3.4.2 Contracts**

3528 As described in sections **Participation in a SOA Ecosystem** view and **Realization of a SOA**  
3529 **Ecosystem** view, there are several types of contractual information in the SOA ecosystem. From the  
3530 management perspective, three basic types of the contractual information relate to:

- 3531 • relationship between service provider and consumer;
- 3532 • communication with the service;

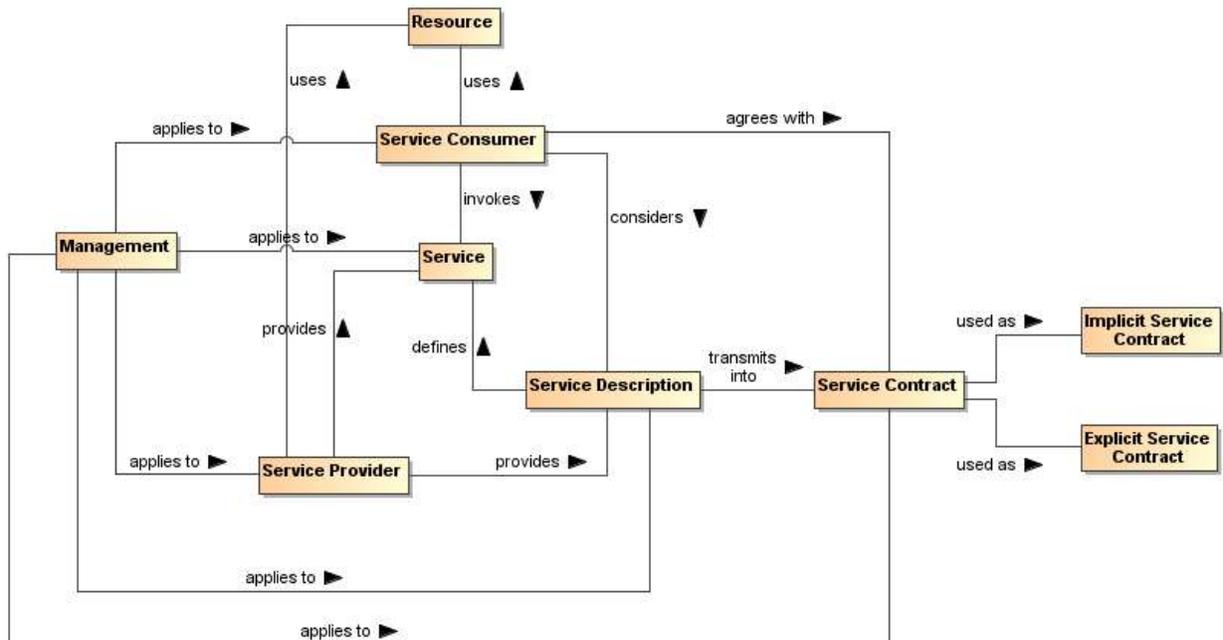

3533 • control of the quality of the service execution.  
 3534 When a consumer prepares to interact with a service, the consumer and the service provider must come  
 3535 to an agreement on the service features and characteristics that will be provided by the service and made  
 3536 available to the consumer. This agreement is known as a service contract.

3537 **Service Contract**

3538 An implicit or explicit documented agreement between the service **consumer** and service  
 3539 **provider** about the use of the service based on  
 3540 • the commitment by a service provider to provide service functionality and results consistent  
 3541 with identified **real world effects** and  
 3542 • the commitment by a service **consumer** to interact with the service per specific means and  
 3543 per specified **policies**,  
 3544 where both consumer and provider actions are in the manner described in the service description.

3545 The service description provides the basis for the service contract and, in some situations, may be used  
 3546 as an implicit default service contract. In addition, the service description may set mandatory aspects of a  
 3547 service contract, e.g. for security services, or may specify acceptable alternatives. As an example of  
 3548 alternatives, the service description may identify which versions of a vocabulary will be recognized, and  
 3549 the specifics of the contract are satisfied when the consumer uses one of the alternatives. Another  
 3550 alternative could have a consumer identify a policy they require be satisfied, e.g. a standard privacy policy  
 3551 on handling personal information, and a provider that is prepared to accept a policy request would  
 3552 indicate acceptance as part of the service contract by continuing with the interaction. In each of these  
 3553 cases, the actions of the participants are consistent with an implicit service contract without the existence  
 3554 of a formal agreement between the participants.

3555 In the case of business services, it is anticipated that the service contract may take an explicit form and  
 3556 the agreement between business consumer and business service provider is formalized. Formalization  
 3557 requires up-front interactions between service consumer and service provider. In many business  
 3558 interactions, especially between business organizations within or across corporate boundaries, a  
 3559 consumer must have a contractual assurance from the provider or wants to explicitly indicate choices  
 3560 among alternatives, e.g., only use a subset of the business functionality offered by the service and pay a  
 3561 prorated  
 3562 cost.

3563  
 3564 *Figure 44 - Management of the service interaction*

3565 Consequently, an implicit service contract is an agreement (1) on the consumer side with the terms,  
 3566 conditions, features and interaction means specified in the service description "as is" or (2) a selection

3567 from alternatives that are made available through mechanisms included in the service description, and  
3568 neither of these require any a priori interactions between the service consumer and the service provider.  
3569 For example, a browser interface may display a checked box indicating the consumer agrees to accept  
3570 future advertisement; the consumer can uncheck the box to indicate advertisements should not be sent.

3571 An explicit service contract always requires a form of interaction between the service consumer and the  
3572 service provider prior to the service invocation. This interaction may regard the choice or selection of the  
3573 subset of the elements of the service description or other alternatives introduced through the formal  
3574 agreement process that would be applicable to the interaction with the service and affect related joint  
3575 action.

3576 Any form of explicit contract couples the service consumer and provider. While explicit contracts may be  
3577 necessary or desirable in some cases, such as in supply chain management, commerce often uses a mix  
3578 of implicit and explicit contracts, and a service provider may offer (via service description) a conditional  
3579 shift from implicit to explicit contract. For example, Twitter offers an implicit contract on the use of its APIs  
3580 to any application with the limit on the amount of service invocations; if the application has to use more  
3581 invocations, one has to enter into the explicit fee-based contract with the provider. A case where an  
3582 implicit contract transforms into an explicit contract may be illustrated when one buys a new computer and  
3583 it does not work. The buyer returns the computer for repair under the manufacturer's warranty as stated  
3584 by an implicit purchase contract. However, if the repair does not fix the problem and the seller offers an  
3585 upgraded model in replacement, the buyer may agree to an explicit contract that limits the rights of the  
3586 buyer to make the explicit agreement public.

3587 Control of the quality of the service execution, often represented as a service level agreement (SLA), is  
3588 performed by service monitoring systems and includes both technical and operational business controls.  
3589 SLA is a part of the service contract and, because of the individual nature of such contracts, may vary  
3590 from one service contract to another, even for the same consumer. Typically, a particular SLA in the  
3591 service contract is a concrete instance of the SLA declared in the service description.

3592 Management of the service contracts is based on management policies that may be mentioned in the  
3593 service description and in the service contracts. Management of the service contracts is mandatory for  
3594 consumer relationship management. In the case of explicit service contracts, the contracts have to be  
3595 created, stored, maintained, reviewed/controlled and archived/destroyed as needed. All the activities are  
3596 management concerns. Explicit service contracts may be stored in specialized repositories that provide  
3597 appropriate level of security.

3598 Management of the service interfaces is based on several management policies that regulate

- 3599 • availability of interfaces specified in the service contracts,
- 3600 • accessibility of interfaces,
- 3601 • procedures for interface changes,
- 3602 • interface versions as well as the versions of all parts of the interfaces,
- 3603 • traceability of the interfaces and their versions back to the service description document.

3604 Management of the SLA is integral to the management of service monitoring and operational service  
3605 behavior at run-time. An SLA usually enumerates service characteristics and expected performances of  
3606 the service. Since an SLA carries the connotation of a 'promise', monitoring is needed to know if the  
3607 promise is being kept. Existence of an SLA itself does not guarantee that the consumer will be provided  
3608 with the service level specified in the service contract.

3609 The use of an SLA in a SOA ecosystem can be wider than just an agreement on technical performances.  
3610 An SLA may contain remedies for situations where the promised service cannot be maintained, or the  
3611 real world effect cannot be achieved due to developments subsequent to the agreement. A service  
3612 consumer that acts accordingly to realize the real world effect may be compensated for the breach of the  
3613 SLA if the effect is not realized.

3614 Management of the SLA includes, among others, policies to change, update, and replace the SLA. This  
3615 aspect concerns service Execution Context because the business logic associated with a defined  
3616 interface may differ in different Execution Contexts and affect the overall performance of the service.

### 3617 **5.3.4.3 Policies**

3618 "Although provision of management capabilities enables a service to become manageable, the extent and  
3619 degree of permissible management are defined in management policies that are associated with the  
3620 services. Management policies are used to define the obligations for, and permissions to, managing the  
3621 service" [WSA]. Management policies, in essence, are the realization of governing rules and regulations.  
3622 As such, some management policies may target services while other policies may target the management  
3623 of the services.

3624 In practice, a policy without any means of enforcing it is vacuous. In the case of management policy, we  
3625 rely on a management infrastructure to realize and enforce management policy.

### 3626 **5.3.4.4 Service Description and Management**

3627 The service description identifies several management objects such as a set of service interfaces and  
3628 related set of SLAs. Service behavioral characteristics and performances specified in the SLA depend on  
3629 the interface type and its Execution Context. In the service description, a service consumer can find  
3630 references to management policies, SLA metrics, and the means of accessing measured values that  
3631 together increase assurance in the service quality. At the same time, service description is an artifact that  
3632 must be managed.

3633 In the SOA ecosystem, the service description is the assembled information that describes the service but  
3634 it may be reported or displayed in different presentations. While each separate version of the service has  
3635 one and only one service description, different categories of service consumers may focus their interests  
3636 on different aspects of the service description. Thus, the same service description may be displayed not  
3637 only in different languages but also with different cultural and professional accents in the content.

3638 New service description may be issued to reflect changes and update in the service. If the change in the  
3639 service does not affect its service description, the new service version may have the same service  
3640 description as the previous version except for the updated version identifier. For example, a service  
3641 description may stay the same if bugs were fixed in the service. However, if a change in the service  
3642 influences any aspects of the service quality that can affect the real world effect resulting from  
3643 interactions with the service, the service description must reflect this change even if there are no changes  
3644 to the service interface.

3645 Management of the service description as well as of the explicit service contracts is essential for delivery  
3646 of the service to the consumer satisfaction. This management can also prevent business problems rooted  
3647 in poor communication between the service consumers and the service providers.

3648 Thus, management of service description contains, among others, management of the service description  
3649 presentations, the life-cycles of the service descriptions, service description distribution practices and  
3650 storage of the service descriptions and related service contracts. Collections of service descriptions in the  
3651 enterprise may manifest a need for specialized registries and/or repositories. Depending on the enterprise  
3652 policies, an allocation of purposes and duties of registries and repositories may vary but this topic is  
3653 beyond the current scope.

### 3654 **5.3.5 Management for Monitoring and Reporting**

3655 The successful application of management relies on the monitoring and reporting aspects of management  
3656 to enable the control aspect. Monitoring in the context of management consists of measuring values of  
3657 managed aspects and evaluating that measurement in relationship to some expectation. Monitoring in a  
3658 SOA ecosystem is enabled through the use of mechanisms by resources for exposing managed aspects.  
3659 In the SOA framework, this mechanism may be a service for obtaining the measurement. Alternatively,  
3660 the measurement may be monitored by means of event generation containing updated values of the  
3661 managed aspect.

3662 Approaches to monitoring may use a polling strategy in which the measurements are requested from  
3663 resources in periodic intervals, in a pull strategy in which the measurements are requested from  
3664 resources at random times, or in a push strategy in which the measurements are supplied by the resource  
3665 without request. The push strategy can be used in a periodic update approach or in an 'update on  
3666 change' approach. Management services must be capable of handling these different approaches to  
3667 monitoring.

3668 Reporting is the complement to monitoring. Where monitoring is responsible for obtaining measurements,  
3669 reporting is responsible for distributing those measurements to interested stakeholders. The separation  
3670 between monitoring and reporting is made to include the possibility that data obtained through monitoring  
3671 might not be used until an event impacting the ecosystem occurs or the measurement requires further  
3672 processing to be useful. In the SOA framework, reporting is provided using services for requesting  
3673 measurement reports. These reports may consist of raw measurement data, formatted collections of data,  
3674 or the results of analysis performed on measurement data from collections of different managed aspects.  
3675 Reporting is also used to support logging and auditing capabilities, where the reporting mechanisms  
3676 create log or audit entries.

### 3677 **5.3.6 Management for Infrastructure**

3678 All of the properties, policies, interactions, resources, and management are only possible if a SOA  
3679 ecosystem infrastructure provides support for managed capabilities. Each managed capability imposes  
3680 different requirements on the capabilities supplied by the infrastructure in SOA ecosystem and requires  
3681 that those capabilities be usable as services or at the very least be interoperable.

3682 While not providing a full list of infrastructural elements of a SOA ecosystem, we list some examples here:

- 3683 1. Registries and repositories for services, policies, and related descriptions and contracts
- 3684 2. Synchronous and asynchronous communication channels for service interactions (e.g., network,  
3685 e-mail, message routing with ability of mediating transport protocols, etc.)
- 3686 3. Recovery capabilities
- 3687 4. Security controls

3688 A SOA ecosystem infrastructure, enabling service management, should also support:

- 3689 1. Management enforcement and control means
- 3690 2. Monitoring and SLA validation controls
- 3691 3. Testing and Reporting capabilities

3692 The combination of manageability properties, related capabilities and infrastructure elements constitutes  
3693 a certain level of SOA management maturity. While several maturity models exist, this topic is out of the  
3694 scope of the current document.

### 3695 **5.3.7 Architectural Implication of the SOA Management**

3696 SOA Management is one of the fundamental elements of the SOA ecosystem; it impacts all aspects of a  
3697 service life-cycle, service activities and actions, and a service usage. The key choices that must be made  
3698 center on management means, methods and manageability properties:

- 3699 • Every resource of the SOA ecosystem and, particularly, services **MUST** provide manageability  
3700 properties
  - 3701 ○ The set of manageability properties **SHOULD** include as minimum such properties as life-  
3702 cycle, combination, configuration, event monitoring, performance, quality of services, and  
3703 policy manageability
  - 3704 ○ Combinations of manageability properties **MAY** be used in different management  
3705 methods and tools
- 3706 • Manageability properties and applicable policies **SHOULD** be appropriately described in the  
3707 services description and contracts
- 3708 • Management processes **SHOULD** operate (control, enforce and provide a feedback to the  
3709 governance) via policies, agreements/contracts, and practices defined through governance
- 3710 • Management functions and information **MAY** be realized as services and, thus, **MUST** be  
3711 managed itself
- 3712 • Management in the cases, where sufficient guidance is unavailable or for which agreement  
3713 between all stakeholders cannot be reached, **MUST** be flexible and adaptable to handle  
3714 unanticipated conditions without unnecessarily breaking trust relationships
- 3715 • Management **SHOULD** engage a monitoring mechanism to enable manageability. Monitoring  
3716 **MUST** include
  - 3717 ○ Access mechanisms to collected SLA metrics

- 3718 ○ Assessment mechanisms to compare metrics against policies and contracts
- 3719 ● Results of monitoring and reporting **MUST** be made accessible to participants in different
- 3720 ownership domains.

## 3721 5.4 SOA Testing Model

3722 Testing for SOA combines the typical challenges of software testing and certification with the addition of  
3723 accommodating the distributed nature and independence of the **resources**, the greater access of a more  
3724 unbounded consumer population, and the desired flexibility to create new solutions from existing  
3725 components over which the solution developer has little if any control. The **purpose** of testing is to  
3726 demonstrate a required level of reliability, correctness, and effectiveness that enable prospective  
3727 consumers to have adequate confidence in using a service. Adequacy is defined by the consumer based  
3728 on the consumer's needs and context of use. Absolute correctness and completeness cannot be proven  
3729 by testing; however, for SOA, it is critical for the prospective consumer to know what testing has been  
3730 performed, how it has been performed, and what were the results.

### 3731 5.4.1 Traditional Software Testing as Basis for SOA Testing

3732 SOA services are largely software artifacts and can leverage the body of experience that has evolved  
3733 around software testing. **[IEEE 829]** specifies the basic set of software test documents while allowing  
3734 flexibility for tailored use. Many testing frameworks are available but the SOA-RAF does not prescribe the  
3735 use of any one in particular and choice will be driven by a framework that offers the right amount and  
3736 level of testing. As such, IEEE-829 can provide guidance to SOA testing and a point of reference for  
3737 additional test concerns introduced by a SOA approach.

3738 IEEE-829 covers test specification and test reporting through use of several document types, including  
3739 test plans; test design, test case, and test procedure specifications; and documents to identify, log, and  
3740 report on test occurrences and artifacts. In summary, IEEE-829 captures (1) what was tested, (2) how it  
3741 was tested, e.g. the test procedure used, and (3) the results of the test. While the SOA-RAF does not  
3742 require IEEE-829 artifacts, those with responsibilities for testing should consider how aspects of IEEE-  
3743 829 apply.

#### 3744 5.4.1.1 Types of Testing

3745 There are numerous aspects of testing that, in total, work to establish that an entity is (1) built as required  
3746 per policies and related specifications prescribed by the entity's owner, and (2) delivers the functionality  
3747 required by its intended users. This is often referred to as verification and validation.

3748 In Section 4.4, Policies are described that can be related to testing. These policies may prescribe but are  
3749 not limited to the business processes to be followed. Policies may also prescribe the standards with which  
3750 an implementation must comply, as well as the **qualifications** of and restrictions on the users. In addition  
3751 to the functional requirements prescribing what an entity does, there may also be non-functional  
3752 performance and/or quality metrics that state how well the entity performs. The relation of these policies  
3753 to SOA testing is discussed further below.

3754 The identification of policies is the purview of governance (section 5.1) and the assuring of compliance  
3755 (including response to noncompliance) with policies is a matter for management (section 5.3).

#### 3756 5.4.1.2 Range of Test Conditions

3757 Test conditions and expected responses are detailed in the test case specification. The test conditions  
3758 should be designed to cover the areas for which the entity's response must be documented and may  
3759 include:

- 3760 ● nominal conditions
- 3761 ● boundaries and extremes of expected conditions
- 3762 ● breaking point where the entity has degraded below a certain level or has otherwise ceased
- 3763 effective functioning
- 3764 ● random conditions to investigate unidentified dependencies among combinations of conditions
- 3765 ● errors conditions to test error handling

3766 The specification of how each of these conditions should be tested for SOA resources, including the  
3767 infrastructure elements of the SOA ecosystem, is beyond the scope of this document but is an area that  
3768 evolves along with operational SOA experience.

## 3769 **5.4.2 Testing and the SOA Ecosystem**

3770 Testing of SOA artifacts for use in the SOA ecosystem differs from traditional software testing for several  
3771 reasons. These include a difference in what constitutes the consumer community and what constitutes  
3772 the evolving environment that comprises the SOA ecosystem. In response, testing must include  
3773 considerations for making a service testable throughout its lifetime.

### 3774 **5.4.2.1 Testing and the Consumer Communities**

3775 A highly touted benefit of SOA is to enable unanticipated consumers to make use of services for  
3776 unanticipated purposes. Examples of this could include the consumer using a service for a result that  
3777 was not considered the primary one by the provider or the service may be used in combination with other  
3778 services in a scenario that is different from the one considered when designing for the initial target  
3779 consumer community. It is unlikely that a new consumer will push the services back to anything  
3780 resembling the initial test phase to test the new use, and thus additional paradigms for testing are  
3781 necessary. The potential [responsibilities](#) related to such "consumer testing" are discussed further below.

3782 In addition to consumers who interact with a service to realize the described [real world effects](#), the  
3783 developer community is also intended to be a consumer. In the SOA vision of reuse, the developer  
3784 composes new solutions using existing services, where the existing services provide desired [real world](#)  
3785 [effects](#) that are needed by the new solution. The composed solution must be tested for its intended  
3786 functionality, and the component service may need particular attention if its use is different from its typical  
3787 use as a separate offering. Note, the composition developer is not expected to own a private copy of a  
3788 component service, and testing may be dependent on test interfaces provided by the component service.

### 3789 **5.4.2.2 Testing and the Evolving SOA Ecosystem**

3790 The distributed, unbounded nature of the SOA ecosystem makes it unlikely to have an isolated test  
3791 environment that duplicates the operational environment. A traditional testing approach often makes use  
3792 of a test system that is identical to the eventual operational system but isolated for testing. After testing is  
3793 successfully completed, the tested entity would be migrated to the operational environment, or the test  
3794 environment may be delivered as part of the system to become operational. This is not feasible for the  
3795 SOA ecosystem as a whole.

3796 SOA services must be testable in the environment and under the conditions that can be encountered in  
3797 the operational SOA ecosystem. As the ecosystem is in constant change, so some level of testing is  
3798 continuous through the lifetime of the service, leveraging utility services used by the ecosystem  
3799 infrastructure to monitor its own health and respond to situations that could lead to degraded  
3800 performance. This implies the test resources must incorporate aspects of the SOA paradigm, and a  
3801 category of services may be created to specifically support and enable effective monitoring and  
3802 continuous testing for [resources](#) participating in the SOA ecosystem.

3803 While SOA within an enterprise may represent a more constrained and predictable operational  
3804 environment, the composability and unanticipated use aspects are highly touted within the enterprise.  
3805 The expanded perspective on testing may not be as demanding within an enterprise but fuller  
3806 consideration of the ecosystem enables the enterprise to be more responsive should conditions change.

## 3807 **5.4.3 Elements of SOA Testing**

3808 IEEE-829 emphasizes identifying what is to be tested, how it is to be tested, and by whom the testing is to  
3809 be done. This is equally applicable to SOA testing.

### 3810 **5.4.3.1 What is to be Tested**

3811 The focus of this discussion is the SOA service. It is recognized that the infrastructure components of  
3812 any SOA environment are likely to also be SOA services and, as such, falls under the same testing

3813 guidance. Other resources that contribute to a SOA environment may not be SOA services, but are  
3814 expected to satisfy the intent if not the letter of guidance presented here.

3815 The following discussion often focuses on a singular SOA service but it is implicit that any service may be  
3816 a composite of other services. As such, testing the functionality of a composite service may effectively be  
3817 testing an end-to-end business process that is being provided by the composite service. If new versions  
3818 are available for the component services, appropriate end-to-end testing of the composite may be  
3819 required in order to verify that the composite functionality is still adequately provided. The level of  
3820 required testing of an updated composite service depends on policies of those providing the service,  
3821 policies of those using the service, and mission criticality of those depending on the service results.

3822 The Service Description model (*Figure 16*) elaborates on described aspects of a service:

- 3823 • the service functionality and technical assumptions that underlie the functionality;
- 3824 • the policies that describe conditions of use;
- 3825 • the service interface that defines information exchange with the service;
- 3826 • service reachability that identifies how and where message exchange is to occur; and
- 3827 • metrics access for any [participant](#) to have information on how a service is performing.

3828 The aspects represent joint concerns of all the stakeholders, and service testing must provide adequate  
3829 assurance that each of these aspects is operational as defined. In particular:

- 3830 • Service functionality is an early and ongoing focus of testing to ensure the service accurately  
3831 reflects the described functionality and the described functionality accurately addresses the  
3832 consumer needs.
- 3833 • Policies constraining service development, such as coding standards and best practices, require  
3834 appropriate testing and auditing during development to ensure compliance. Policies that define  
3835 conditions of use are initially tested during service development and are continuously monitored  
3836 during the operational lifetime of the service.
- 3837 • At any point where the interface is modified or exposes a new [resource](#), the message exchange  
3838 should be monitored both to ensure the message reaches its intended destination and it is parsed  
3839 correctly once received.
- 3840 • The service interface is also tested when the service endpoint changes. Functioning of a service  
3841 endpoint at one time does not guarantee it is functioning at another time, e.g. the server with the  
3842 endpoint address may be down, making testing of service reachability a continual monitoring  
3843 function through the life of the service's use of the endpoint.
- 3844 • Metrics are a key indicator for consumers to decide if a service is adequate for their needs. For  
3845 instance, the average response time or the recent availability can be determining factors even if  
3846 there are no rules or regulations promulgated through the governance process against which  
3847 these metrics are assessed. Testing will ensure that the metrics access indicated in the service  
3848 description is accurate.

3849 The individual test requirements highlight aspects of the service that testing must consider but testing  
3850 must establish more than isolated behavior. The emphasis is the holistic results of interacting with the  
3851 service in the SOA environment. Recall that the execution context is the set of agreements between a  
3852 consumer and a provider that define the conditions under which service interaction occurs. Variations in  
3853 the execution context require monitoring to ensure that different combinations of conditions perform  
3854 together as desired. For example, if a new privacy policy takes additional [resources](#) to apply, this may  
3855 affect quality of service and propagate other effects. These could not be tested during the original testing  
3856 if the alternate policy did not exist at that time.

### 3857 **5.4.3.2 How Testing is to be Done**

3858 Testing should follow well-defined methodologies and, if possible, should reuse test artifacts that have  
3859 proven generally useful for past testing. For example, IEEE-829 notes that test cases are separated from  
3860 test designs to allow for use in more than one design and to allow for reuse in other situations. As with  
3861 description of a service in the SOA ecosystem, description of testing artifacts enables awareness of the  
3862 artifact and describes how the artifact may be accessed or used.

3863 As with traditional testing, the specific test procedures and test case inputs are important so the tests are  
3864 unambiguously defined and entities can be retested in the future. Automated testing and regression  
3865 testing may be more important in the SOA ecosystem in order to re-verify a service is still acceptable

3866 when incorporated in a new use. For example, if a new use requires the services to deal with input  
3867 parameters outside the range of initial testing, the tests could be rerun with the new parameters. If the  
3868 testing resources (e.g. services that support re-executing test cases) are available to consumers within  
3869 the SOA ecosystem, the testing as designed by test professionals could be consumed through a service  
3870 accessed by consumers, and their results could augment those already in place. This is discussed  
3871 further in the next section.

### 3872 **5.4.3.3 Who Performs the Testing**

3873 As with any software, the first line of testing is unit testing done by software developers. It is likely that  
3874 initial testing will be done by those developing the software but may also be done independently by other  
3875 developers. For SOA development, unit testing is likely confined to a development sandbox isolated from  
3876 the SOA ecosystem.

3877 SOA testing will differ from traditional software testing in that testing beyond the development sandbox  
3878 must incorporate aspects of the SOA ecosystem, and those doing the testing must be familiar with both  
3879 the characteristics and responses of the ecosystem and the tools, especially those available as services,  
3880 to facilitate and standardize testing. Test professionals will know what level of assurance must be  
3881 established as the exposure of the service to the ecosystem and ecosystem to the service increases  
3882 towards operational status. These test professionals may be internal resources to an organization or may  
3883 evolve as a separate discipline provided through external contracting.

3884 As noted above, it is unlikely that a complete duplicate of the SOA ecosystem will be available for isolated  
3885 testing, and thus use of ecosystem [resources](#) will manifest as a transition process rather than a step  
3886 change from a test environment to an operational one. This is especially true for new composite services  
3887 that incorporate existing operational services to achieve the new functionality. The test professionals will  
3888 need to understand the available resources and the ramifications of this transition.

3889 As with current software development, a stage beyond work by test professionals will make use of a  
3890 select group of typical users (commonly referred to as beta testers) to report on service response during  
3891 typical intended use. This establishes fitness by the consumers, providing final validation of previously  
3892 verified processes, requirements, and final implementation.

3893 In traditional software development, beta testing is the end of testing for a given version of the software.  
3894 However, although the initial test phase can establish an appropriate level of confidence consistent with  
3895 the designed use for the initial target consumer community, the operational service will exist in an  
3896 evolving ecosystem, and later conditions of use may differ from those thought to be sufficient during the  
3897 initial testing. Thus, operational monitoring becomes an extension of testing through the service lifetime.  
3898 This continuous testing will attempt to ensure that a service does not consume an inordinate amount of  
3899 ecosystem resources or display other behavior that degrades the ecosystem, but it will not undercover  
3900 functional errors that may surface over time.

3901 As with any software, it is the responsibility of the consumers to consider the reasonableness of solutions  
3902 in order to spot errors in either the software or the way the software is being used. This is especially  
3903 important for consumers with unanticipated uses that may go beyond the original test conditions. It is  
3904 unlikely the consumers will initiate a new round of formal testing unless the new use requires a  
3905 significantly higher level of confidence in the service. Rather the consumer becomes a new extension to  
3906 the testing regiment. Obvious testing would include a sanity check of results during the new use.  
3907 However, if the details of legacy testing are associated with the service through the service description  
3908 and if testing resources are available through automated testing services, then the new consumers can  
3909 rerun and extend previous testing to include the extended test conditions. If the test results are  
3910 acceptable, these can be added to the documentation of previous results and become the extended basis  
3911 for future decisions by prospective consumers on the appropriateness of the service. If the results are not  
3912 acceptable or in some way questionable, the responsible party for the service or testing professionals can  
3913 be brought in to decide if remedial action is necessary.

### 3914 **5.4.3.4 How Testing Results are Reported**

3915 For any SOA service, an accurate reporting of the testing a service has undergone and the results of the  
3916 testing is vital to consumers deciding whether a service is appropriate for intended use. Appropriateness  
3917 may be defined by a consumer organization and require specific test regiments culminating in a

3918 certification; appropriateness could be established by accepting testing and certifications that have been  
3919 conferred by others.

3920 The testing and certification information should be identified in the service description. Referring to the  
3921 general description model of *Figure 14*, tests conducted by or under a request from the service owner (see  
3922 [ownership](#) in section 3.2.4) would be captured under Annotations from Owners. Testing done by others  
3923 (such as consumers with unanticipated uses) could be associated through Annotations from 3rd Parties.

3924 Consumer testing and the reporting of results raise additional issues. While stating who did the testing is  
3925 mandatory, there may be formal requirements for authentication of the tester to ensure traceability of the  
3926 testing claims. In some circumstances, persons or organizations would not be allowed to state testing  
3927 claims unless the tester was an approved entity. In other cases, ensuring the tester had a valid email  
3928 may be sufficient. In either case, it would be at the discretion of the potential consumer to decide what  
3929 level of authentication was acceptable and which testers are considered authoritative in the context of  
3930 their anticipated use.

3931 Finally, in a world of openly shared information, we would see an ever-expanding set of testing  
3932 information as new uses and new consumers interact with a service. In reality, these new uses may  
3933 represent proprietary processes or classified use that should only be available to authorized parties.  
3934 Testing information, as with other elements of description, may require special access controls to ensure  
3935 appropriate access and use.

#### 3936 **5.4.4 Testing SOA Services**

3937 Testing of SOA services should be consistent with the SOA paradigm. In particular, testing resources  
3938 and artifacts should be visible in support of service interaction between providers and consumers, where  
3939 here the interaction is between the testing resource and the tester. In addition, the idea of opacity of the  
3940 implementation should limit the details that need to be available for effective use of the test resources.

3941 Software testing is a gradual exercise going from micro inspection to testing macro effects. A typical  
3942 testing process is likely to begin with the traditional code reviews. SOA considerations would account for  
3943 the distributed nature of SOA, including issues of distributed security and best practices to ensure secure  
3944 resources.

3945 Code review is likely followed by unit testing in a development sandbox isolated from the operational  
3946 environment. The unit testing is done with full knowledge of the service internal structure and knowledge  
3947 of resources representing underlying capabilities. Some aspects of testing may require external  
3948 dependencies be satisfied, and this is often done using substitutes that mimic some aspects of the  
3949 performance of an operational service without committing to the [real world effects](#) that the operational  
3950 service would produce. Unit testing includes tests of the service interface to ensure exchanged messages  
3951 are as specified in the service description and the messages can be parsed and interpreted as intended.  
3952 Unit testing also verifies intended functionality and that the software has dealt correctly with internal  
3953 dependencies, such as access to other dedicated resources.

3954 After unit testing has demonstrated an adequate level of confidence in the service, the testing must  
3955 transition from the tightly controlled environment of the development sandbox to an environment that  
3956 more closely resembles the operational SOA ecosystem or, at a minimum, the intended enterprise. While  
3957 sandbox testing will substitute for some interactions with the SOA environment, such as an interface to a  
3958 security service without the security service functionality, the dynamic nature of SOA makes a full  
3959 simulation infeasible to create or maintain. This is especially true when a new composite service makes  
3960 use of operational services provided by others. Thus, at some point before testing is complete, the  
3961 service will need to demonstrate its functionality by using resources and dealing with conditions that only  
3962 exist in the full ecosystem or the intended enterprise. Some of these resources may still provide test  
3963 interfaces but the interfaces will be accessible using the SOA environment and not just implemented for  
3964 the sandbox.

3965 At this stage, the opacity of the service becomes important as the details of interacting with the service  
3966 now rely on correct use of the service interface and not knowledge of the service internals. The workings  
3967 of the service will only be observable through the [real world effects](#) realized through service interactions  
3968 and external indications that conditions of use, such as user authentication, are satisfied. Monitoring the  
3969 behavior of the service will depend on service interfaces that expose internal monitoring or provide  
3970 required information to the SOA infrastructure monitoring function. The monitoring required to test a new

3971 service is likely to have significant overlap with the monitoring the SOA infrastructure includes to monitor  
3972 its own health and to identify and isolate behavior outside of acceptable bounds. This is exactly what is  
3973 needed as part of service testing, and it is reasonable to assume that the ecosystem transition includes  
3974 use of operational monitoring rather than solely dedicated monitoring for each service being tested. Use  
3975 of SOA monitoring resources during the explicit testing phase sets the stage for monitoring and a level of  
3976 continual testing throughout the service lifetime.

3977 In summary, consider the example of a new composite service that combines the [real world effects](#) and  
3978 complies with the conditions of use of five existing operational services. The developer of the composite  
3979 service does not own any of the component services and has limited, if any, ability to get the distributed  
3980 owners to do any customization. The developer also is limited by the principle of opacity to information  
3981 comprising the service description, and does not know internal details of the component services. The  
3982 developer of the composite service must use the component services as they exist as part of the SOA  
3983 environment, including what is provided to support testing by new users.

#### 3984 **5.4.5 Architectural Implications for SOA Testing**

3985 The discussion of SOA Testing indicates numerous architectural implications that **MUST** be considered  
3986 for testing of resources and interactions within the SOA ecosystem:

- 3987 • SOA services **MUST** be testable in the environment and under the conditions that can be  
3988 encountered in the operational SOA ecosystem.
- 3989 • The distributed, boundary-less nature of the SOA ecosystem makes it infeasible to create and  
3990 maintain a single testing substitute of the entire ecosystem to support testing activities. Test  
3991 protocols **MUST** recognize and accommodate for changes to and activities within the ecosystem.
- 3992 • A standard suite of monitoring services **SHOULD** be defined, developed, and maintained. This  
3993 **SHOULD** be done in a manner consistent with the evolving nature of the ecosystem.
- 3994 • Services **SHOULD** provide interfaces that support access in a test mode.
- 3995 • Testing resources **MUST** be described and their descriptions **MUST** be catalogued in a manner  
3996 that enables their discovery and access.
- 3997 • Guidelines for testing and ecosystem access **MUST** be established and the ecosystem **MUST** be  
3998 able to enforce those guidelines asserted as policies.
- 3999 • Services **SHOULD** be available to support automated testing and regression testing.
- 4000 • Services **SHOULD** be available to facilitate updating service description by authorized  
4001 participants who has performed testing of a service.

---

## 4002 6 Conformance

### 4003 6.1 Conformance Targets

4004 This Reference Architecture Foundation is an abstract architectural description of Service Oriented  
4005 Architecture. As such, tests of conformance to the RAF should be concerned primarily with adherence to  
4006 principles rather than technical details such as prescribed syntax or coding conventions. Relevant  
4007 principles are set out in the RAF through

- 4008 - the modeling of concepts and relationships (defining what it means to realize, own, and use SOA-  
4009 based systems and have such systems participate in a SOA ecosystem); and
- 4010 - a series of Architectural Implications.

4011 The discussion of concepts and relationships that elaborate the SOA principles in each of the main  
4012 sections above culminates in an 'Architectural Implications' section (sections 3.4, 4.1.4, 4.2.3, 4.3.6,  
4013 4.4.3, 5.1.4, 5.2.5, 5.3.7, and 5.4.5), where these sections contain formal conformance requirements  
4014 ("MAY", "MUST", "SHOULD") in accordance with [RFC 2119].

4015 In discussing conformance, we use the term **SOA-RAF Target Architecture** to identify the (typically  
4016 concrete) architecture that may be considered as conforming to the abstract principles outlined in this  
4017 document.

#### 4018 **SOA-RAF Target Architecture**

4019 An architectural description of a system that is intended to be viewed as conforming to the  
4020 SOA-RAF

4021 While we cannot guarantee interoperability between target architectures (or more specifically between  
4022 applications and systems residing within the ecosystems of those target architectures), the likelihood of  
4023 interoperability between target architectures is increased by conformance to this Reference Architecture  
4024 Framework as it facilitates semantic engagement between the different ecosystems.

### 4025 6.2 Conformance and Architectural Implications

4026 The SOA-RAF focuses on concepts, and the relationships between them, that are needed to enable  
4027 SOA-based systems to be realized, owned, and used. The Architectural Implications reflect specific  
4028 elements that will be reflected in a more concrete architecture based on the SOA-RAF.

4029 Conformance can therefore be measured both in terms of how a SOA-RAF Target Architecture uses the  
4030 concepts and models outlined in the SOA-RAF; and how the various Architectural Implications have been  
4031 addressed.

### 4032 6.3 Conformance Summary

4033 Concepts described in the RAF **SHOULD** be expressed and used in the target architecture. If used, such  
4034 expression **MUST** reflect the relationships identified within this document.

4035 Terminology within the target architecture **SHOULD** be identical to that in the RAF and the terms used  
4036 refer to the same concepts; and any graph of concepts and relationships between them that *are* used  
4037 **MUST** be consistent with the RAF.

4038 The SOA-RAF Target Architecture **MUST** take account of the Architectural Implications in the sections  
4039 listed above.

---

4040 **Appendix A. Acknowledgements**

4041 The following individuals have participated in the work of the technical committee responsible for creation  
4042 of this specification and are gratefully acknowledged:

4043 **Participants:**

4044 Chris Bashioum, MITRE Corporation  
4045 Rex Brooks, Individual Member  
4046 Peter F Brown, Individual Member  
4047 Scott Came, Search Group Inc.  
4048 Joseph Chiusano, Booz Allen Hamilton  
4049 Robert Ellinger, Northrop Grumman Corporation  
4050 David Ellis, Sandia National Laboratories  
4051 Jeff A. Estefan, Jet Propulsion Laboratory  
4052 Don Flinn, Individual Member  
4053 Anil John, Johns Hopkins University  
4054 Ken Laskey, MITRE Corporation  
4055 Boris Lublinsky, Nokia Corporation  
4056 Francis G. McCabe, Individual Member  
4057 Christopher McDaniels, USSTRATCOM  
4058 Tom Merkle, Lockheed Martin Corporation  
4059 Jyoti Namjoshi, Patni Computer Systems Ltd.  
4060 Duane Nickull, Adobe Inc.  
4061 James Odell, Associate  
4062 Michael Poulin, Fidelity Investments  
4063 Kevin Smith, Individual Member  
4064 Michael Stiefel, Associate  
4065 Danny Thornton, Northrop Grumman  
4066 Timothy Vibbert, Lockheed Martin Corporation  
4067 Robert Vitello, New York Dept. of Labor

4068 The committee would particularly like to underline the significant writing and conceptualization  
4069 contributions made by Chris Bashioum, Rex Brooks, Peter Brown, Dave Ellis, Jeff Estefan, Ken Laskey,  
4070 Boris Lublinsky, Frank McCabe, Michael Poulin, Kevin Smith and Danny Thornton

## Appendix C. Relationship to other SOA Open Standards

4075  
4076  
4077  
4078

Numerous efforts have been working in the space of defining standards for SOA and its applications. The OASIS SOA-RM Technical Committee and its SOA-RA Sub-Committee has established communications with several of these efforts in an attempt to coordinate and facilitate among the efforts. This appendix notes some of these efforts.

4079  
4080

### C.1 Navigating the SOA Open Standards Landscape Around Architecture

4081  
4082  
4083  
4084

The white paper *Navigating the SOA Open Standards Landscape Around Architecture* issued jointly by OASIS, OMG, and The Open Group **[SOA NAV]** was written to help the SOA community at large navigate the myriad of overlapping technical products produced by these organizations with specific emphasis on the 'A' in SOA, i.e., Architecture.

4085  
4086  
4087  
4088  
4089

The white paper explains and positions standards for SOA reference models, ontologies, reference architectures, maturity models, modeling languages, and standards work on SOA governance. It outlines where the works are similar, highlights the strengths of each body of work, and touches on how the work can be used together in complementary ways. It is also meant as a guide to users for selecting those specifications most appropriate for their needs.

4090  
4091  
4092  
4093  
4094

While the understanding of SOA and SOA Governance concepts provided by these works is similar, the evolving standards are written from different perspectives. Each specification supports a similar range of opportunity, but has provided different depths of detail for the perspectives on which they focus. Although the definitions and expressions may differ, there is agreement on the fundamental concepts of SOA and SOA Governance.

4095

The following is a summary taken from **[SOA NAV]** of the positioning and guidance on the specifications:

4096  
4097  
4098  
4099  
4100  
4101  
4102  
4103  
4104  
4105  
4106  
4107  
4108  
4109  
4110  
4111  
4112  
4113  
4114  
4115  
4116  
4117  
4118  
4119  
4120  
4121

- The OASIS Reference Model for SOA (SOA RM) is, by design, the most abstract of the specifications positioned. It is used for understanding core SOA concepts
- The Open Group SOA Ontology extends, refines, and formalizes some of the core concepts of the SOA RM. It is used for understanding core SOA concepts and facilitates a model-driven approach to SOA development.
- The OASIS Reference Architecture Foundation for SOA (this document) is an abstract, foundational reference architecture addressing a broader ecosystem viewpoint for building and interacting within the SOA paradigm. It is used for understanding different elements of SOA, the completeness of SOA architectures and implementations, and considerations for reaching across ownership boundaries where there is no single authoritative entity for SOA and SOA governance.
- The Open Group SOA Reference Architecture is a layered architecture from consumer and provider perspective with cross cutting concerns describing these architectural building blocks and principles that support the realizations of SOA. It is used for understanding the different elements of SOA, deployment of SOA in enterprise, basis for an industry or organizational reference architecture, implication of architectural decisions, and positioning of vendor products in a SOA context.
- The Open Group SOA Governance Framework is a governance domain reference model and method. It is for understanding SOA governance in organizations. The OASIS Reference Architecture for SOA Foundation contains an abstract discussion of governance principles as applied to SOA across boundaries
- The Open Group SOA Integration Maturity Model (OSIMM) is a means to assess an organization's maturity within a broad SOA spectrum and define a roadmap for incremental adoption. It is used for understanding the level of SOA maturity in an organization
- The Object Management Group SoaML Specification supports services modeling UML extensions. It can be seen as an instantiation of a subset of the Open Group RA used for representing SOA artifacts in UML.

4122 Fortunately, there is a great deal of agreement on the foundational core concepts across the many  
 4123 independent specifications and standards for SOA. This can be best explained by broad and common  
 4124 experience of users of SOA and its maturity in the marketplace. It also provides assurance that investing  
 4125 in SOA-based business and IT transformation initiatives that incorporate and use these specifications and  
 4126 standards helps to mitigate risks that might compromise a successful SOA solution.

## C.2 The Service-Aware Interoperability Framework: Canonical

Readers of the RAF are strongly encouraged to review a document recently published by the Health Level Seven (HL7) Architecture Board (ArB) entitled *The Service-Aware Interoperability Framework: Canonical*. The document was developed over the past four years, and represents a substantive, industry-specific effort (i.e. the large but vertical healthcare industry) to surface, define, and discuss in detail various aspects of a number of critical success factors involved in implementing large-scale (i.e. enterprises-level) architectures with a focus on achieving both intra- and inter-enterprise technical interoperability irrespective of the particular exchange mechanism involved, e.g. service interface, messages, or structure documents.

In addition to providing an independent validation for the both the general focus as well as some of the specifics of the RAF (especially those involving the importance of governance in achieving large-scale interoperability), the HL7 document underscores several important aspects of the RAF including:

1. A validation of one of the RAF's primary claims, i.e. the need to specifically focus on intra- and inter-enterprise interoperability as a first-class citizen in any enterprise (or cross-enterprise) architecture discussion irrespective of the particular choice of enterprise architecture approach, framework, or implementation technology, e.g. TOGAF, Zachman, ODP, SOA, etc. In addition, the HL7 document clearly articulates – as the RAF does as well – the difficulties involved in achieving that focus in such

- 4147 a manner that it can be manifest in operationally effective and manageable processes and  
4148 deliverables.
- 4149 2. An agreement as to the critical importance of governance as the root of any successful effort to  
4150 implement large-scale, cross-boundary interoperability aimed at achieving a collective shared mission  
4151 or goal. In particular, both documents share the notion that 'technical-level' governance – e.g. service  
4152 – or message-level technical interchange specifications – must itself be a manifestation of a higher-  
4153 level, cross-jurisdictional agreement on desired goals, responsibilities, accountabilities, and  
4154 deliverables.
  - 4155 3. A validation of the importance of core SOA constructs as constructs useful in expressing many of the  
4156 central aspects of interoperability irrespective of whether a particular interoperability scenario is  
4157 actually 'realized' using SOA-compatible technologies. (NOTE: Although it might at first appear that  
4158 the OASIS document is more 'service-focused' than the 'service-aware' document from HL7, there  
4159 are considerably more similarities than differences in these slightly different foci secondary to the fact  
4160 that both documents are intent on describing principles and framework concepts rather than delving  
4161 into technical details. There are, however, certain instances where content of the OASIS document  
4162 would be likely to find its analogue in SAIF Implementation Guides rather than in the SAIF Canonical  
4163 Definition document.)
  - 4164 4. The need for specific, explicit statements of those aspects of a given component that affects its ability  
4165 to participate in a reliable, predictable manner in a variety of interoperability scenarios. In particular,  
4166 component characteristics must be explicitly expressed in both design-time and run-time contexts as  
4167 implicit assumptions are the root of most failures to achieve successfully cross-boundary  
4168 interoperability irrespective of the chosen technical details of a particular interoperability instance.

4169 In summary, although the two documents are clearly not identical in their specifics, e.g. there are  
4170 differences in the language used to name various concepts, constructs, and relationships; there are some  
4171 differences in levels of abstraction regarding certain topics, etc.; and although the OASIS RAF is more  
4172 directly focused on services as a final implementation architecture than the HL7 SAIF CD, the  
4173 commonalities of purpose, content, and approach present in the two documents – documents which were  
4174 developed by each organization without any knowledge of the others' work in what clearly are areas of  
4175 common interest and concern – far outweighs their differences. As such, the HL7 ArB and the OASIS  
4176 RAF Task Force have agreed to work together going forward to obtain the highest degree of alignment  
4177 and harmonization possible between the two documents including the possible development of a joint  
4178 document under the auspices of one of the ISO software engineering threads.

4179 The current version of the HL7 document – as well as all future versions – is available at:  
4180 <http://www.hl7.org/permalink/?SAIFCDR1PUBLIC>

### 4181 **C.3 IEEE Reference Architecture**

4182 As the RAF has been finalized, a new initiative has appeared from the Institute of Electrical and  
4183 Electronics Engineers (IEEE) to develop a SOA Reference Architecture. Encouragingly, the working  
4184 group established decided not to start from scratch but instead take account of existing work. Its initial  
4185 phase of work is currently ongoing (Summer 2012) and is concentrating on assessing both the current  
4186 RAF and The Open Group's SOA Reference Architecture. The desire at this stage is to endorse these  
4187 two works rather than to create a new one.

### 4188 **C.4 RM-ODP**

4189 The Reference Model for Open Distributed Processing (the RM-ODP) is an international standard  
4190 developed by the ISO and ITU-T standardization organizations [**ISO/IEC 10746**]. It provides a set of  
4191 concepts and structuring rules for describing and building open distributed systems, structured in terms of  
4192 five viewpoints, representing concerns of different stakeholders.

4193 From an architectural point of view, there is no significant difference between service-oriented  
4194 architectures (SOA) and the architectural framework defined in ODP. Some argue that current service-  
4195 oriented approaches can be understood as a subset of the more general ODP approach [LININGTON].  
4196 Many of the concepts and principles in the RAF and the RM-ODP are indeed closely aligned.

4197 In common with the RAF, RM-ODP uses the Viewpoint construct of **[ISO/IEC 42010]** in order to articulate  
4198 the work, context and concepts.

4199 There is a danger of over-simplifying the comparison and losing some of the important mapping between  
4200 the concepts in the two works but a high-level comparison follows.

4201 The **enterprise viewpoint** and the **information viewpoint** share many aspects in common with the  
4202 RAF's SOA Ecosystem view and its associated models and are mainly concerned with: understanding,  
4203 defining and modeling organizational context in which a distributed system is to be built and operated;  
4204 defines how sets of participants should behave in order to achieve specific objectives; roles played;  
4205 processes and interactions involved; enterprise policies (obligations, permissions, prohibitions,  
4206 authorizations) that constrain behavior in different roles; and descriptions of behavior expressing  
4207 functionality or capability provided by one party to others who can use the service to satisfy their own  
4208 business needs, resulting in an added value to them.

4209 The **computational viewpoint** maps closely to the RAF Service Model and is concerned with describing  
4210 basic functionality of the processes and applications supporting enterprise activities. They are both  
4211 concerned with interactions at interfaces between and across organizational or ownership boundaries.

4212 The RM-ODP standard also provides a well-defined **conformance framework**, providing links between  
4213 specifications and implementations and thus supporting testing and which corresponds to the RAF's  
4214 Architectural Implications sections.

4215 The ODP viewpoint languages are defined in abstract way and can be supported by several notations.  
4216 The use of UML notation in expressing ODP viewpoint languages is defined in a separate ISO standard,  
4217 *Use of UML for ODP system specification* ('UML4ODP' for short) **[ISO/IEC IS 19793]**.
