**Abstract:**

This specification describes enhancements to SOAP messaging to provide message integrity and confidentiality. The specified mechanisms can be used to accommodate a wide variety of security models and encryption technologies.

This specification also provides a general-purpose mechanism for associating security tokens with message content. No specific type of security token is required, the specification is designed to be extensible (i.e.. support multiple security token formats). For example, a client might provide one format for proof of identity and provide another format for proof that they have a particular business certification.

Additionally, this specification describes how to encode binary security tokens, a framework for XML-based tokens, and how to include opaque encrypted keys. It also includes extensibility mechanisms that can be used to further describe the characteristics of the tokens that are included with a message.

**Status:**

This is a technical committee document submitted for consideration by the OASIS Web Services Security (WSS) technical committee. Please send comments to the editors. If you are on the [wss@lists.oasis-open.org](mailto:wss@lists.oasis-open.org) list for committee members, send comments there. If you are not on that list, subscribe to the [wss-comment@lists.oasis-open.org](mailto:wss-comment@lists.oasis-open.org) list and send comments there. To subscribe, send an email message to [wss-comment-request@lists.oasis-open.org](mailto:wss-comment-request@lists.oasis-open.org) with the word "subscribe" as the body of the message. For patent disclosure information that may be essential to the implementation of this specification, and any offers of licensing terms, refer to the Intellectual Property Rights section of the OASIS Web Services Security Technical Committee (WSS TC) web page at <http://www.oasis-open.org/committees/wss/ipr.php>. General OASIS IPR information can be found at <http://www.oasis-open.org/who/intellectualproperty.shtml>.

# 111 1 Introduction

112 This specification proposes a standard set of SOAP [SOAP11, SOAP12] extensions that can be  
113 used when building secure Web services to implement message content integrity and  
114 confidentiality. This specification refers to this set of extensions and modules as the “Web  
115 Services Security: SOAP Message Security” or “WSS: SOAP Message Security”.

116 This specification is flexible and is designed to be used as the basis for securing Web services  
117 within a wide variety of security models including PKI, Kerberos, and SSL. Specifically, this  
118 specification provides support for multiple security token formats, multiple trust domains, multiple  
119 signature formats, and multiple encryption technologies. The token formats and semantics for  
120 using these are defined in the associated profile documents.

121 This specification provides three main mechanisms: ability to send security tokens as part of a  
122 message, message integrity, and message confidentiality. These mechanisms by themselves do  
123 not provide a complete security solution for Web services. Instead, this specification is a building  
124 block that can be used in conjunction with other Web service extensions and higher-level  
125 application-specific protocols to accommodate a wide variety of security models and security  
126 technologies.

127 These mechanisms can be used independently (e.g., to pass a security token) or in a tightly  
128 coupled manner (e.g., signing and encrypting a message or part of a message and providing a  
129 security token or token path associated with the keys used for signing and encryption).

## 130 1.1 Goals and Requirements

131 The goal of this specification is to enable applications to conduct secure SOAP message  
132 exchanges.

133 This specification is intended to provide a flexible set of mechanisms that can be used to  
134 construct a range of security protocols; in other words this specification intentionally does not  
135 describe explicit fixed security protocols.

136 As with every security protocol, significant efforts must be applied to ensure that security  
137 protocols constructed using this specification are not vulnerable to any one of a wide range of  
138 attacks. The examples in this specification are meant to illustrate the syntax of these mechanisms  
139 and are not intended as examples of combining these mechanisms in secure ways.

140 The focus of this specification is to describe a single-message security language that provides for  
141 message security that may assume an established session, security context and/or policy  
142 agreement.

143 The requirements to support secure message exchange are listed below.

### 144 1.1.1 Requirements

145 The Web services security language must support a wide variety of security models. The  
146 following list identifies the key driving requirements for this specification:

- 147 • Multiple security token formats
- 148 • Multiple trust domains
- 149 • Multiple signature formats
- 150 • Multiple encryption technologies
- 151 • End-to-end message content security and not just transport-level security

### 152 1.1.2 Non-Goals

153 The following topics are outside the scope of this document:

- 154 • Establishing a security context or authentication mechanisms.
- 155 • Key derivation.
- 156 • Advertisement and exchange of security policy.

- 157 • How trust is established or determined.
- 158 • Non-repudiation.
- 159

---

## 2 Notations and Terminology

160

This section specifies the notations, namespaces, and terminology used in this specification.

161

### 2.1 Notational Conventions

162

The keywords "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119.

163

164

165

When describing abstract data models, this specification uses the notational convention used by the XML Infoset. Specifically, abstract property names always appear in square brackets (e.g., [some property]).

166

167

168

When describing concrete XML schemas, this specification uses a convention where each member of an element's [children] or [attributes] property is described using an XPath-like notation (e.g., /x:MyHeader/x:SomeProperty/@value1). The use of {any} indicates the presence of an element wildcard (<xs:any/>). The use of @{any} indicates the presence of an attribute wildcard (<xs:anyAttribute/>).

169

170

171

172

173

174

Readers are presumed to be familiar with the terms in the Internet Security Glossary [GLOS].

### 2.2 Namespaces

175

Namespace URIs (of the general form "some-URI") represents some application-dependent or context-dependent URI as defined in RFC 2396 [URI]. The XML namespace URIs that MUST be used by implementations of this specification are as follows (note that elements used in this specification are from various namespaces):

176

177

178

179

180

```
http://www.docs.oasis-open.org/wss/2004/01/oasis-200401-wss-  
wssecurity-secext-1.0.xsd  
http://www.docs.oasis-open.org/wss/2004/01/oasis-200401-wss-  
wssecurity-utility-1.0.xsd
```

181

182

183

184

185

This specification is designed to work with the general SOAP [SOAP11, SOAP12] message structure and message processing model, and should be applicable to any version of SOAP. The current SOAP 1.1 namespace URI is used herein to provide detailed examples, but there is no intention to limit the applicability of this specification to a single version of SOAP.

186

187

188

189

The namespaces used in this document are shown in the following table (note that for brevity, the examples use the prefixes listed below but do not include the URIs – those listed below are assumed).

190

191

192

193

Prefix	Namespace
ds	http://www.w3.org/2000/09/xmldsig#
S11	http://schemas.xmlsoap.org/soap/envelope/
S12	http://www.w3.org/2003/05/soap-envelope
wsse	http://www.docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-secext-1.0.xsd
wsu	http://www.docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-utility-1.0.xsd

xenc	<a href="http://www.w3.org/2001/04/xmlenc#">http://www.w3.org/2001/04/xmlenc#</a>
------	---

194 The URLs provided for the *wsse* and *wsu* namespaces can be used to obtain the schema files.

## 195 **2.3 Acronyms and Abbreviations**

196 The following (non-normative) table defines acronyms and abbreviations for this document.

Term	Definition
HMAC	Keyed-Hashing for Message Authentication
SHA-1	Secure Hash Algorithm 1
SOAP	Simple Object Access Protocol
URI	Uniform Resource Identifier
XML	Extensible Markup Language

## 197 **2.4 Terminology**

198 Defined below are the basic definitions for the security terminology used in this specification.

199 **Claim** – A *claim* is a declaration made by an entity (e.g. name, identity, key, group, privilege,  
200 capability, etc).

201 **Claim Confirmation** – A *claim confirmation* is the process of verifying that a claim applies to  
202 an entity

203 **Confidentiality** – *Confidentiality* is the property that data is not made available to  
204 unauthorized individuals, entities, or processes.

205 **Digest** – A *digest* is a cryptographic checksum of an octet stream.

206 **Digital Signature** – In this document, digital signature and signature are used  
207 interchangeably and have the same meaning.

208 **End-To-End Message Level Security** – *End-to-end message level security* is  
209 established when a message that traverses multiple applications (one or more SOAP  
210 intermediaries) within and between business entities, e.g. companies, divisions and business  
211 units, is secure over its full route through and between those business entities. This includes not  
212 only messages that are initiated within the entity but also those messages that originate outside  
213 the entity, whether they are Web Services or the more traditional messages.

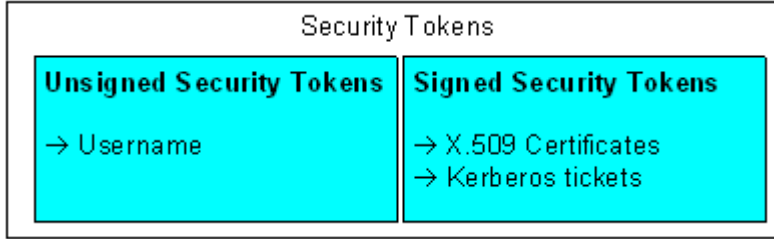

214 **Integrity** – *Integrity* is the property that data has not been modified.

215 **Message Confidentiality** - *Message Confidentiality* is a property of the message and  
216 encryption is the mechanism by which this property of the message is provided.

217 **Message Integrity** - *Message Integrity* is a property of the message and digital signature is a  
218 mechanism by which this property of the message is provided.

219 **Signature** - A *signature* is a value computed with a cryptographic algorithm and bound  
220 to data in such a way that intended recipients of the data can use the signature to verify that the  
221 data has not been altered and/or has originated from the signer of the message, providing  
222 message integrity and authentication. The signature can be computed and verified with  
223 symmetric key algorithms, where the same key is used for signing and verifying, or with  
224 asymmetric key algorithms, where different keys are used for signing and verifying (a private and  
225 public key pair are used).

226 **Security Token** – A *security token* represents a collection (one or more) of claims.  
227

228  
229  
230  
231  
232  
233  
234  
235  
236

**Signed Security Token** – A *signed security token* is a security token that is asserted and cryptographically signed by a specific authority (e.g. an X.509 certificate or a Kerberos ticket).  
**Trust** - *Trust* is the characteristic that one entity is willing to rely upon a second entity to execute a set of actions and/or to make set of assertions about a set of subjects and/or scopes.

237

---

## 3 Message Protection Mechanisms

238

When securing SOAP messages, various types of threats should be considered. This includes, but is not limited to:

239

240

- the message could be modified or read by antagonists or

241

- an antagonist could send messages to a service that, while well-formed, lack appropriate security claims to warrant processing.

242

243

To understand these threats this specification defines a message security model.

244

### 3.1 Message Security Model

245

This document specifies an abstract *message security model* in terms of security tokens combined with digital signatures to protect and authenticate SOAP messages.

246

247

Security tokens assert claims and can be used to assert the binding between authentication secrets or keys and security identities. An authority can vouch for or endorse the claims in a

248

249

security token by using its key to sign or encrypt (it is recommended to use a keyed encryption)

250

the security token thereby enabling the authentication of the claims in the token. An X.509 [X509]

251

certificate, claiming the binding between one's identity and public key, is an example of a signed security token endorsed by the certificate authority. In the absence of endorsement by a third

252

253

party, the recipient of a security token may choose to accept the claims made in the token based

254

on its trust of the producer of the containing message.

255

Signatures are used to verify message origin and integrity. Signatures are also used by message producers to demonstrate knowledge of the key, typically from a third party, used to confirm the

256

257

claims in a security token and thus to bind their identity (and any other claims occurring in the

258

security token) to the messages they create.

259

It should be noted that this security model, by itself, is subject to multiple security attacks. Refer

260

to the Security Considerations section for additional details.

261

Where the specification requires that an element be "processed" it means that the element type

262

MUST be recognized to the extent that an appropriate error is returned if the element is not

263

supported.

264

### 3.2 Message Protection

265

Protecting the message content from being disclosed (confidentiality) or modified without

266

detection (integrity) are primary security concerns. This specification provides a means to protect a message by encrypting and/or digitally signing a body, a header, or any combination of them (or

267

268

parts of them).

269

Message integrity is provided by XML Signature [XMLSIG] in conjunction with security tokens to

270

ensure that modifications to messages are detected. The integrity mechanisms are designed to

271

support multiple signatures, potentially by multiple SOAP actors/roles, and to be extensible to

272

support additional signature formats.

273

Message confidentiality leverages XML Encryption [XMLENC] in conjunction with security tokens

274

to keep portions of a SOAP message confidential. The encryption mechanisms are designed to

275

support additional encryption processes and operations by multiple SOAP actors/roles.

276

This document defines syntax and semantics of signatures within a `<wsse:Security>` element.

277

This document does not specify any signature appearing outside of a `<wsse:Security>`

278

element.

279

### 3.3 Invalid or Missing Claims

280

A message recipient SHOULD reject messages containing invalid signatures, messages missing

281

necessary claims or messages whose claims have unacceptable values. Such messages are

282

unauthorized (or malformed). This specification provides a flexible way for the message producer

283 to make a claim about the security properties by associating zero or more security tokens with the  
284 message. An example of a security claim is the identity of the producer; the producer can claim  
285 that he is Bob, known as an employee of some company, and therefore he has the right to send  
286 the message.

### 287 3.4 Example

288 The following example illustrates the use of a custom security token and associated signature.  
289 The token contains base64 encoded binary data conveying a symmetric key which, we assume,  
290 can be properly authenticated by the recipient. The message producer uses the symmetric key  
291 with an HMAC signing algorithm to sign the message. The message receiver uses its knowledge  
292 of the shared secret to repeat the HMAC key calculation which it uses to validate the signature  
293 and in the process confirm that the message was authored by the claimed user identity.

```
294  
295 (001) <?xml version="1.0" encoding="utf-8"?>  
296 (002) <S11:Envelope xmlns:S11="..." xmlns:wsse="..." xmlns:wsu="..."

310 (011)         <ds:SignatureMethod  
311           Algorithm=  
312             "http://www.w3.org/2000/09/xmldsig#hmac-shal" />  
313 (012)         <ds:Reference URI="#MsgBody">  
314 (013)           <ds:DigestMethod  
315             Algorithm=  
316               "http://www.w3.org/2000/09/xmldsig#sha1" />  
317 (014)           <ds:DigestValue>LyLsF0Pi4wPU...</ds:DigestValue>  
318 (015)         </ds:Reference>  
319 (016)       </ds:SignedInfo>  
320 (017)     <ds:SignatureValue>DJbchm5gK...</ds:SignatureValue>  
321 (018)     <ds:KeyInfo>  
322 (019)       <wsse:SecurityTokenReference>  
323 (020)         <wsse:Reference URI="#MyID" />  
324 (021)       </wsse:SecurityTokenReference>  
325 (022)     </ds:KeyInfo>  
326 (023)   </ds:Signature>  
327 (024) </wsse:Security>  
328 (025) </S11:Header>  
329 (026) <S11:Body wsu:Id="MsgBody">  
330 (027)   <tru:StockSymbol xmlns:tru="http://fabrikam123.com/payloads">  
331     QQQ  
332   </tru:StockSymbol>  
333 (028) </S11:Body>  
334 (029) </S11:Envelope>
```

336 The first two lines start the SOAP envelope. Line (003) begins the headers that are associated  
337 with this SOAP message.

338 Line (004) starts the <wsse:Security> header defined in this specification. This header  
339 contains security information for an intended recipient. This element continues until line (024).

340 Lines (005) to (007) specify a custom token that is associated with the message. In this case, it  
341 uses an externally defined custom token format.  
342 Lines (008) to (023) specify a digital signature. This signature ensures the integrity of the signed  
343 elements. The signature uses the XML Signature specification identified by the ds namespace  
344 declaration in Line (002).  
345 Lines (009) to (016) describe what is being signed and the type of canonicalization being used.  
346 Line (010) specifies how to canonicalize (normalize) the data that is being signed. Lines (012) to  
347 (015) select the elements that are signed and how to digest them. Specifically, line (012)  
348 indicates that the <S11:Body> element is signed. In this example only the message body is  
349 signed; typically all critical elements of the message are included in the signature (see the  
350 Extended Example below).  
351 Line (017) specifies the signature value of the canonicalized form of the data that is being signed  
352 as defined in the XML Signature specification.  
353 Lines (018) to (022) provides information, partial or complete, as to where to find the security  
354 token associated with this signature. Specifically, lines (019) to (021) indicate that the security  
355 token can be found at (pulled from) the specified URL.  
356 Lines (026) to (028) contain the body (payload) of the SOAP message.  
357

358

## 4 ID References

359 There are many motivations for referencing other message elements such as signature  
360 references or correlating signatures to security tokens. For this reason, this specification defines  
361 the `wsu:Id` attribute so that recipients need not understand the full schema of the message for  
362 processing of the security elements. That is, they need only "know" that the `wsu:Id` attribute  
363 represents a schema type of ID which is used to reference elements. However, because some  
364 key schemas used by this specification don't allow attribute extensibility (namely XML Signature  
365 and XML Encryption), this specification also allows use of their local ID attributes in addition to  
366 the `wsu:Id` attribute. As a consequence, when trying to locate an element referenced in a  
367 signature, the following attributes are considered:

- 368 • Local ID attributes on XML Signature elements
- 369 • Local ID attributes on XML Encryption elements
- 370 • Global `wsu:Id` attributes (described below) on elements

371 In addition, when signing a part of an envelope such as the body, it is RECOMMENDED that an  
372 ID reference is used instead of a more general transformation, especially XPath [XPath]. This is  
373 to simplify processing.

### 4.1 Id Attribute

374  
375 There are many situations where elements within SOAP messages need to be referenced. For  
376 example, when signing a SOAP message, selected elements are included in the scope of the  
377 signature. XML Schema Part 2 [XMLSCHEMA] provides several built-in data types that may be  
378 used for identifying and referencing elements, but their use requires that consumers of the SOAP  
379 message either have or must be able to obtain the schemas where the identity or reference  
380 mechanisms are defined. In some circumstances, for example, intermediaries, this can be  
381 problematic and not desirable.

382 Consequently a mechanism is required for identifying and referencing elements, based on the  
383 SOAP foundation, which does not rely upon complete schema knowledge of the context in which  
384 an element is used. This functionality can be integrated into SOAP processors so that elements  
385 can be identified and referred to without dynamic schema discovery and processing.

386 This section specifies a namespace-qualified global attribute for identifying an element which can  
387 be applied to any element that either allows arbitrary attributes or specifically allows a particular  
388 attribute.

### 4.2 Id Schema

389 To simplify the processing for intermediaries and recipients, a common attribute is defined for  
390 identifying an element. This attribute utilizes the XML Schema ID type and specifies a common  
391 attribute for indicating this information for elements.

392 The syntax for this attribute is as follows:

```
393  
394  
395 <anyElement wsu:Id="...">...</anyElement>
```

396  
397 The following describes the attribute illustrated above:

398 `.../@wsu:Id`

399 This attribute, defined as type `xsd:ID`, provides a well-known attribute for specifying the  
400 local ID of an element.

401 Two `wsu:Id` attributes within an XML document MUST NOT have the same value.

402 Implementations MAY rely on XML Schema validation to provide rudimentary enforcement for  
403 intra-document uniqueness. However, applications SHOULD NOT rely on schema validation  
404 alone to enforce uniqueness.

405 This specification does not specify how this attribute will be used and it is expected that other  
406 specifications MAY add additional semantics (or restrictions) for their usage of this attribute.  
407 The following example illustrates use of this attribute to identify an element:

408  
409  
410  
411

```
<x:myElement wsu:Id="ID1" xmlns:x="..."  
            xmlns:wsu="..." />
```

412 Conformant processors that do support XML Schema MUST treat this attribute as if it was  
413 defined using a global attribute declaration.  
414 Conformant processors that do not support dynamic XML Schema or DTDs discovery and  
415 processing are strongly encouraged to integrate this attribute definition into their parsers. That is,  
416 to treat this attribute information item as if its PSVI has a [type definition] which {target  
417 namespace} is "http://www.w3.org/2001/XMLSchema" and which {name} is "Id." Doing so  
418 allows the processor to inherently know *how* to process the attribute without having to locate and  
419 process the associated schema. Specifically, implementations MAY support the value of the  
420 `wsu:Id` as the valid identifier for use as an XPointer [XPointer] shorthand pointer for  
421 interoperability with XML Signature references.

422

## 5 Security Header

423 The `<wsse:Security>` header block provides a mechanism for attaching security-related  
424 information targeted at a specific recipient in the form of a SOAPactor/role. This may be either  
425 the ultimate recipient of the message or an intermediary. Consequently, elements of this type  
426 may be present multiple times in a SOAP message. An active intermediary on the message path  
427 MAY add one or more new sub-elements to an existing `<wsse:Security>` header block if they  
428 are targeted for its SOAP node or it MAY add one or more new headers for additional targets.  
429 As stated, a message MAY have multiple `<wsse:Security>` header blocks if they are targeted  
430 for separate recipients. However, only one `<wsse:Security>` header block MAY omit the S11:  
431 actor or S12:role attributes. Two `<wsse:Security>` header blocks MUST NOT have the  
432 same value for S11:actor or S12:role. Message security information targeted for different  
433 recipients MUST appear in different `<wsse:Security>` header blocks. This is due to potential  
434 processing order issues (e.g. due to possible header re-ordering). The `<wsse:Security>`  
435 header block without a specified S11:actor or S12:role MAY be processed by anyone, but  
436 MUST NOT be removed prior to the final destination or endpoint.

437 As elements are added to a `<wsse:Security>` header block, they SHOULD be prepended to  
438 the existing elements. As such, the `<wsse:Security>` header block represents the signing and  
439 encryption steps the message producer took to create the message. This prepending rule  
440 ensures that the receiving application can process sub-elements in the order they appear in the  
441 `<wsse:Security>` header block, because there will be no forward dependency among the sub-  
442 elements. Note that this specification does not impose any specific order of processing the sub-  
443 elements. The receiving application can use whatever order is required.

444 When a sub-element refers to a key carried in another sub-element (for example, a signature  
445 sub-element that refers to a binary security token sub-element that contains the X.509 certificate  
446 used for the signature), the key-bearing element SHOULD be ordered to precede the key-using  
447 Element:

448

449

```
449 <S11:Envelope>  
450   <S11:Header>  
451     ...  
452     <wsse:Security S11:actor="..." S11:mustUnderstand="...">  
453       ...  
454     </wsse:Security>  
455     ...  
456   </S11:Header>  
457   ...  
458 </S11:Envelope>
```

459

460 The following describes the attributes and elements listed in the example above:

461

*/wsse:Security*

This is the header block for passing security-related message information to a recipient.

463

*/wsse:Security/@S11:actor*

This attribute allows a specific SOAP 1.1 [SPOAP11] actor to be identified. This attribute is optional; however, no two instances of the header block may omit a actor or specify the same actor.

467

*/wsse:Security/@S12:role*

This attribute allows a specific SOAP 1.2 [SOAP12] role to be identified. This attribute is optional; however, no two instances of the header block may omit a role or specify the same role.

471

472

*/wsse:Security/{any}*

473 This is an extensibility mechanism to allow different (extensible) types of security  
474 information, based on a schema, to be passed. Unrecognized elements SHOULD cause  
475 a fault.

476 */wsse:Security/@{any}*

477 This is an extensibility mechanism to allow additional attributes, based on schemas, to be  
478 added to the header. Unrecognized attributes SHOULD cause a fault.

479 All compliant implementations MUST be able to process a `<wsse:Security>` element.  
480 All compliant implementations MUST declare which profiles they support and MUST be able to  
481 process a `<wsse:Security>` element including any sub-elements which may be defined by that  
482 profile. It is RECOMMENDED that undefined elements within the `<wsse:Security>` header  
483 not be processed.

484 The next few sections outline elements that are expected to be used within a `<wsse:Security>`  
485 header.

486 When a `<wsse:Security>` header includes a `mustUnderstand="true"` attribute:

- 487 • The receiver MUST generate a SOAP fault if does not implement the WSS: SOAP  
488 Message Security specification corresponding to the namespace. Implementation means  
489 ability to interpret the schema as well as follow the required processing rules specified in  
490 WSS: SOAP Message Security.
- 491 • The receiver must generate a fault if unable to interpret or process security tokens  
492 contained in the `<wsse:Security>` header block according to the corresponding WSS:  
493 SOAP Message Security token profiles.
- 494 • Receivers MAY ignore elements or extensions within the `<wsse:Security>` element,  
495 based on local security policy.

496

## 6 Security Tokens

497 This chapter specifies some different types of security tokens and how they are attached to  
498 messages.

### 6.1 Attaching Security Tokens

500 This specification defines the `<wsse:Security>` header as a mechanism for conveying  
501 security information with and about a SOAP message. This header is, by design, extensible to  
502 support many types of security information.  
503 For security tokens based on XML, the extensibility of the `<wsse:Security>` header allows for  
504 these security tokens to be directly inserted into the header.

#### 6.1.1 Processing Rules

506 This specification describes the processing rules for using and processing XML Signature and  
507 XML Encryption. These rules MUST be followed when using any type of security token. Note  
508 that if signature or encryption is used in conjunction with security tokens, they MUST be used in a  
509 way that conforms to the processing rules defined by this specification.

#### 6.1.2 Subject Confirmation

511 This specification does not dictate if and how claim confirmation must be done; however, it does  
512 define how signatures may be used and associated with security tokens (by referencing the  
513 security tokens from the signature) as a form of claim confirmation.

### 6.2 User Name Token

#### 6.2.1 Usernames

516 The `<wsse:UsernameToken>` element is introduced as a way of providing a username. This  
517 element is optionally included in the `<wsse:Security>` header.  
518 The following illustrates the syntax of this element:

519

```
<wsse:UsernameToken wsu:Id="...">  
  <wsse:Username>...</wsse:Username>  
</wsse:UsernameToken>
```

523

524 The following describes the attributes and elements listed in the example above:

525 */wsse:UsernameToken*

526 This element is used to represent a claimed identity.

527 */wsse:UsernameToken/@wsu:Id*

528 A string label for this security token.

529 */wsse:UsernameToken/wsse:Username*

530 This required element specifies the claimed identity.

531 */wsse:UsernameToken/wsse:Username/@{any}*

532 This is an extensibility mechanism to allow additional attributes, based on schemas, to be  
533 added to the `<wsse:Username>` element.

534 */wsse:UsernameToken/{any}*

535 This is an extensibility mechanism to allow different (extensible) types of security  
536 information, based on a schema, to be passed. Unrecognized elements SHOULD cause  
537 a fault.

538 */wsse:UsernameToken/@{any}*

539 This is an extensibility mechanism to allow additional attributes, based on schemas, to be  
540 added to the <wsse:UsernameToken> element. Unrecognized attributes SHOULD  
541 cause a fault.

542 All compliant implementations MUST be able to process a <wsse:UsernameToken> element.  
543 The following illustrates the use of this:

544  
545  
546  
547  
548  
549  
550  
551  
552  
553  
554  
555  
556  
557

```
<S11:Envelope xmlns:S11="..." xmlns:wsse="...">
  <S11:Header>
    ...
    <wsse:Security>
      <wsse:UsernameToken>
        <wsse:Username>Zoe</wsse:Username>
      </wsse:UsernameToken>
    </wsse:Security>
    ...
  </S11:Header>
  ...
</S11:Envelope>
```

## 558 6.3 Binary Security Tokens

### 559 6.3.1 Attaching Security Tokens

560 For binary-formatted security tokens, this specification provides a  
561 <wsse:BinarySecurityToken> element that can be included in the <wsse:Security>  
562 header block.

### 563 6.3.2 Encoding Binary Security Tokens

564 Binary security tokens (e.g., X.509 certificates and Kerberos [KERBEROS] tickets) or other non-  
565 XML formats require a special encoding format for inclusion. This section describes a basic  
566 framework for using binary security tokens. Subsequent specifications MUST describe the rules  
567 for creating and processing specific binary security token formats.

568 The <wsse:BinarySecurityToken> element defines two attributes that are used to interpret  
569 it. The `ValueType` attribute indicates what the security token is, for example, a Kerberos ticket.  
570 The `EncodingType` tells how the security token is encoded, for example `Base64Binary`.

571 The following is an overview of the syntax:

572  
573  
574  
575  
576

```
<wsse:BinarySecurityToken wsu:Id=...
                          EncodingType=...
                          ValueType=.../>
```

577 The following describes the attributes and elements listed in the example above:

578 */wsse:BinarySecurityToken*

579 This element is used to include a binary-encoded security token.

580 */wsse:BinarySecurityToken/@wsu:Id*

581 An optional string label for this security token.

582 */wsse:BinarySecurityToken/@ValueType*

583 The `ValueType` attribute is used to indicate the "value space" of the encoded binary  
584 data (e.g. an X.509 certificate). The `ValueType` attribute allows a URI that defines the  
585 value type and space of the encoded binary data. Subsequent specifications MUST  
586 define the `ValueType` value for the tokens that they define. The usage of `ValueType` is  
587 RECOMMENDED.

588 */wsse:BinarySecurityToken/@EncodingType*

589 The `EncodingType` attribute is used to indicate, using a URI, the encoding format of the  
590 binary data (e.g., `base64` encoded). A new attribute is introduced, as there are issues

591 with the current schema validation tools that make derivations of mixed simple and  
592 complex types difficult within XML Schema. The `EncodingType` attribute is interpreted  
593 to indicate the encoding format of the element. The following encoding formats are pre-  
594 defined (note that the URI fragments are relative to the URI for this specification):  
595

URI	Description
<code>#Base64Binary</code> (default)	XML Schema base 64 encoding

596  
597 `/wsse:BinarySecurityToken/@{any}`  
598 This is an extensibility mechanism to allow additional attributes, based on schemas, to be  
599 added.  
600 All compliant implementations MUST be able to process a `<wsse:BinarySecurityToken>`  
601 element.  
602 When a `<wsse:BinarySecurityToken>` is included in a signature—that is, it is referenced  
603 from a `<ds:Signature>` element—care should be taken so that the canonicalization algorithm  
604 (e.g., Exclusive XML Canonicalization [EXC-C14N]) does not allow unauthorized replacement of  
605 namespace prefixes of the QNames used in the attribute or element values. In particular, it is  
606 RECOMMENDED that these namespace prefixes be declared within the  
607 `<wsse:BinarySecurityToken>` element if this token does not carry the validating key (and  
608 consequently it is not cryptographically bound to the signature).

## 609 **6.4 XML Tokens**

610 This section presents framework for using XML-based security tokens. Profile specifications  
611 describe rules and processes for specific XML-based security token formats.

### 612 **6.4.1 Identifying and Referencing Security Tokens**

613 This specification also defines multiple mechanisms for identifying and referencing security  
614 tokens using the `wsu:Id` attribute and the `<wsse:SecurityTokenReference>` element (as  
615 well as some additional mechanisms). Please refer to the specific profile documents for the  
616 appropriate reference mechanism. However, specific extensions MAY be made to the  
617 `<wsse:SecurityTokenReference>` element.  
618

---

## 7 Token References

619

620 This chapter discusses and defines mechanisms for referencing security tokens.

### 7.1 SecurityTokenReference Element

621

622 A security token conveys a set of claims. Sometimes these claims reside somewhere else and  
623 need to be "pulled" by the receiving application. The `<wsse:SecurityTokenReference>`  
624 element provides an extensible mechanism for referencing security tokens.

625 The `<wsse:SecurityTokenReference>` element provides an open content model for  
626 referencing security tokens because not all tokens support a common reference pattern.  
627 Similarly, some token formats have closed schemas and define their own reference mechanisms.  
628 The open content model allows appropriate reference mechanisms to be used when referencing  
629 corresponding token types.

630 If a `<wsse:SecurityTokenReference>` is used outside of the `<wsse:Security>` header  
631 block the meaning of the response and/or processing rules of the resulting references **MUST** be  
632 specified by the containing element and are out of scope of this specification.

633 The following illustrates the syntax of this element:

634

```
635 <wsse:SecurityTokenReference wsu:Id="...">
```

```
636   ...
```

```
637 </wsse:SecurityTokenReference>
```

638

639 The following describes the elements defined above:

640 */wsse:SecurityTokenReference*

641 This element provides a reference to a security token.

642 */wsse:SecurityTokenReference/@wsu:Id*

643 A string label for this security token reference which names the reference. This attribute  
644 does not indicate the ID of what is being referenced, that **SHOULD** be done using a  
645 fragment URI in a `<wsse:Reference>` element within the  
646 `<wsse:SecurityTokenReference>` element.

647 */wsse:SecurityTokenReference/@wsse:Usage*

648 This optional attribute is used to type the usage of the `<wsse:SecurityToken>`.

649 Usages are specified using URIs and multiple usages **MAY** be specified using XML list  
650 semantics. No usages are defined by this specification.

651 */wsse:SecurityTokenReference/{any}*

652 This is an extensibility mechanism to allow different (extensible) types of security  
653 references, based on a schema, to be passed. Unrecognized elements **SHOULD** cause a  
654 fault.

655 */wsse:SecurityTokenReference/@{any}*

656 This is an extensibility mechanism to allow additional attributes, based on schemas, to be  
657 added to the header. Unrecognized attributes **SHOULD** cause a fault.

658 All compliant implementations **MUST** be able to process a

659 `<wsse:SecurityTokenReference>` element.

660 This element can also be used as a direct child element of `<ds:KeyInfo>` to indicate a hint to  
661 retrieve the key information from a security token placed somewhere else. In particular, it is  
662 **RECOMMENDED**, when using XML Signature and XML Encryption, that a

663 `<wsse:SecurityTokenReference>` element be placed inside a `<ds:KeyInfo>` to reference  
664 the security token used for the signature or encryption.

665 There are several challenges that implementations face when trying to interoperate. Processing  
666 the IDs and references requires the recipient to *understand* the schema. This may be an  
667 expensive task and in the general case impossible as there is no way to know the "schema  
668 location" for a specific namespace URI. As well, the primary goal of a reference is to uniquely

669 identify the desired token. ID references are, by definition, unique by XML. However, other  
670 mechanisms such as "principal name" are not required to be unique and therefore such  
671 references may be not unique.

672 The following list provides a list of the specific reference mechanisms defined in WSS: SOAP  
673 Message Security in preferred order (i.e., most specific to least specific):

- 674 • **Direct References** – This allows references to included tokens using URI fragments and  
675 external tokens using full URIs.
- 676 • **Key Identifiers** – This allows tokens to be referenced using an opaque value that  
677 represents the token (defined by token type/profile).
- 678 • **Key Names** – This allows tokens to be referenced using a string that matches an identity  
679 assertion within the security token. This is a subset match and may result in multiple  
680 security tokens that match the specified name.
- 681 • **Embedded References** - This allows tokens to be embedded (as opposed to a pointer  
682 to a token that resides elsewhere).

## 683 **7.2 Direct References**

684 The `<wsse:Reference>` element provides an extensible mechanism for directly referencing  
685 security tokens using URIs.

686 The following illustrates the syntax of this element:

```
687 <wsse:SecurityTokenReference wsu:Id="...">  
688   <wsse:Reference URI="..." ValueType="..." />  
689 </wsse:SecurityTokenReference>
```

691 The following describes the elements defined above:  
692 */wsse:SecurityTokenReference/wsse:Reference*

693 */wsse:SecurityTokenReference/wsse:Reference*

694 This element is used to identify an abstract URI location for locating a security token.

695 */wsse:SecurityTokenReference/wsse:Reference/@URI*

696 This optional attribute specifies an abstract URI for where to find a security token. If a  
697 fragment is specified, then it indicates the local ID of the token being referenced.

698 */wsse:SecurityTokenReference/wsse:Reference/@ValueType*

699 This optional attribute specifies a URI that is used to identify the *type* of token being  
700 referenced. This specification does not define any processing rules around the usage of  
701 this attribute, however, specifications for individual token types MAY define specific  
702 processing rules and semantics around the value of the URI and how it SHALL be  
703 interpreted. If this attribute is not present, the URI MUST be processed as a normal URI.  
704 The usage of `ValueType` is RECOMMENDED for references with local URIs.

705 */wsse:SecurityTokenReference/wsse:Reference/{any}*

706 This is an extensibility mechanism to allow different (extensible) types of security  
707 references, based on a schema, to be passed. Unrecognized elements SHOULD cause a  
708 fault.

709 */wsse:SecurityTokenReference/wsse:Reference/@{any}*

710 This is an extensibility mechanism to allow additional attributes, based on schemas, to be  
711 added to the header. Unrecognized attributes SHOULD cause a fault.

712 The following illustrates the use of this element:

```
713 <wsse:SecurityTokenReference  
714   xmlns:wsse="...">  
715   <wsse:Reference  
716     URI="http://www.fabrikam123.com/tokens/Zoe" />  
717 </wsse:SecurityTokenReference>
```

719

### 7.3 Key Identifiers

720

Alternatively, if a direct reference is not used, then it is RECOMMENDED to use a key identifier to specify/reference a security token instead of a <ds:KeyName>. A KeyIdentifier is a value that can be used to uniquely identify a security token (e.g. a hash of the important elements of the security token). The exact value type and generation algorithm varies by security token type (and sometimes by the data within the token), Consequently, the values and algorithms are described in the token-specific profiles rather than this specification.

726

The <wsse:KeyIdentifier> element SHALL be placed in the

727

<wsse:SecurityTokenReference> element to reference a token using an identifier. This element SHOULD be used for all key identifiers.

728

729

The processing model assumes that the key identifier for a security token is constant.

730

Consequently, processing a key identifier is simply looking for a security token whose key identifier matches a given specified constant.

731

732

The following is an overview of the syntax:

733

734

```

<wsse:SecurityTokenReference>
  <wsse:KeyIdentifier wsu:Id="..."
                      ValueType="..."
                      EncodingType="...">
    ...
  </wsse:KeyIdentifier>
</wsse:SecurityTokenReference>

```

735

736

737

738

739

740

741

The following describes the attributes and elements listed in the example above:

742

*/wsse:SecurityTokenReference/wsse:KeyIdentifier*

743

This element is used to include a binary-encoded key identifier.

744

*/wsse:SecurityTokenReference/wsse:KeyIdentifier/@wsu:Id*

745

An optional string label for this identifier.

746

*/wsse:SecurityTokenReference/wsse:KeyIdentifier/@ValueType*

747

The optional `ValueType` attribute is used to indicate the type of `KeyIdentifier` being used. Each specific token profile specifies the `KeyIdentifier` types that may be used to refer to tokens of that type. It also specifies the critical semantics of the identifier, such as whether the `KeyIdentifier` is unique to the key or the token. If no value is specified then the key identifier will be interpreted in an application-specific manner.

748

749

750

751

752

753

*/wsse:SecurityTokenReference/wsse:KeyIdentifier/@EncodingType*

754

The optional `EncodingType` attribute is used to indicate, using a URI, the encoding format of the `KeyIdentifier` (`#Base64Binary`). The base values defined in this specification are used (Note that URI fragments are relative to this document's URI):

755

756

757

URI	Description
<code>#Base64Binary</code>	XML Schema base 64 encoding (default)

758

759

*/wsse:SecurityTokenReference/wsse:KeyIdentifier/@{any}*

760

This is an extensibility mechanism to allow additional attributes, based on schemas, to be added.

761

762

### 7.4 Embedded References

763

In some cases a reference may be to an embedded token (as opposed to a pointer to a token that resides elsewhere). To do this, the <wsse:Embedded> element is specified within a

764

<wsse:SecurityTokenReference> element.

765

766

The following is an overview of the syntax:

767

```

768 <wsse:SecurityTokenReference>
769   <wsse:Embedded wsu:Id="...">
770     ...
771   </wsse:Embedded>
772 </wsse:SecurityTokenReference>

```

773  
774 The following describes the attributes and elements listed in the example above:

775 */wsse:SecurityTokenReference/wsse:Embedded*

776 This element is used to embed a token directly within a reference (that is, to create a  
777 *local* or *literal* reference).

778 */wsse:SecurityTokenReference/wsse:Embedded/@wsu:Id*

779 An optional string label for this element. This allows this embedded token to be  
780 referenced by a signature or encryption.

781 */wsse:SecurityTokenReference/wsse:Embedded/{any}*

782 This is an extensibility mechanism to allow any security token, based on schemas, to be  
783 embedded. Unrecognized elements SHOULD cause a fault.

784 */wsse:SecurityTokenReference/wsse:Embedded/@{any}*

785 This is an extensibility mechanism to allow additional attributes, based on schemas, to be  
786 added. Unrecognized attributes SHOULD cause a fault.

787 The following example illustrates embedding a SAML assertion:

```

788 <S11:Envelope xmlns:S11="..." xmlns:wsse="..." xmlns:wsu="...">
789   <S11:Header>
790     <wsse:Security>
791       ...
792       <wsse:SecurityTokenReference>
793         <wsse:Embedded wsu:Id="tok1">
794           <saml:Assertion xmlns:saml="...">
795             ...
796           </saml:Assertion>
797         </wsse:Embedded>
798       </wsse:SecurityTokenReference>
799     </wsse:Security>
800   </S11:Header>
801   ...
802 </S11:Envelope>

```

## 805 7.5 ds:KeyInfo

806 The `<ds:KeyInfo>` element (from XML Signature) can be used for carrying the key information  
807 and is allowed for different key types and for future extensibility. However, in this specification,  
808 the use of `<wsse:BinarySecurityToken>` is the RECOMMENDED mechanism to carry key  
809 material if the key type contains binary data. Please refer to the specific profile documents for the  
810 appropriate way to carry key material.

811 The following example illustrates use of this element to fetch a named key:

```

812 <ds:KeyInfo Id="..." xmlns:ds="http://www.w3.org/2000/09/xmldsig#">
813   <ds:KeyName>CN=Hiroshi Maruyama, C=JP</ds:KeyName>
814 </ds:KeyInfo>

```

## 816 7.6 Key Names

817 It is strongly RECOMMENDED to use `<wsse:KeyIdentifier>` elements. However, if key  
818 names are used, then it is strongly RECOMMENDED that `<ds:KeyName>` elements conform to  
819 the attribute names in section 2.3 of RFC 2253 (this is recommended by XML Signature for  
820 `<ds:X509SubjectName>`) for interoperability.

821 Additionally, e-mail addresses, SHOULD conform to RFC 822:

822  
823

EmailAddress=ckaler@microsoft.com

824

## 8 Signatures

825

Message producers may want to enable message recipients to determine whether a message was altered in transit and to verify that the claims in a particular security token apply to the producer of the message.

826

827

828

Demonstrating knowledge of a confirmation key associated with a token key-claim confirms the accompanying token claims. Knowledge of a confirmation key may be demonstrated using that key to create an XML Signature, for example. The relying party acceptance of the claims may depend on its confidence in the token. Multiple tokens may contain a key-claim for a signature and may be referenced from the signature using a `<wsse:SecurityTokenReference>`. A key-claim may be an X.509 Certificate token, or a Kerberos service ticket token to give two examples.

833

Because of the mutability of some SOAP headers, producers SHOULD NOT use the *Enveloped Signature Transform* defined in XML Signature. Instead, messages SHOULD explicitly include the elements to be signed. Similarly, producers SHOULD NOT use the *Enveloping Signature* defined in XML Signature [XMLSIG].

835

836

837

838

This specification allows for multiple signatures and signature formats to be attached to a message, each referencing different, even overlapping, parts of the message. This is important for many distributed applications where messages flow through multiple processing stages. For example, a producer may submit an order that contains an orderID header. The producer signs the orderID header and the body of the request (the contents of the order). When this is received by the order processing sub-system, it may insert a shippingID into the header. The order sub-system would then sign, at a minimum, the orderID and the shippingID, and possibly the body as well. Then when this order is processed and shipped by the shipping department, a shippedInfo header might be appended. The shipping department would sign, at a minimum, the shippedInfo and the shippingID and possibly the body and forward the message to the billing department for processing. The billing department can verify the signatures and determine a valid chain of trust for the order, as well as who authorized each step in the process.

843

844

845

846

847

848

849

850

All compliant implementations MUST be able to support the XML Signature standard.

851

852

### 8.1 Algorithms

853

This specification builds on XML Signature and therefore has the same algorithm requirements as those specified in the XML Signature specification.

854

855

The following table outlines additional algorithms that are strongly RECOMMENDED by this specification:

856

857

Algorithm Type	Algorithm	Algorithm URI
Canonicalization	Exclusive XML Canonicalization	<a href="http://www.w3.org/2001/10/xml-exc-c14n#">http://www.w3.org/2001/10/xml-exc-c14n#</a>

858

859

As well, the following table outlines additional algorithms that MAY be used:

Algorithm Type	Algorithm	Algorithm URI
Transform	SOAP Message Normalization	<a href="http://www.w3.org/TR/2003/NOTE-soap12-n11n-20030328/">http://www.w3.org/TR/2003/NOTE-soap12-n11n-20030328/</a>

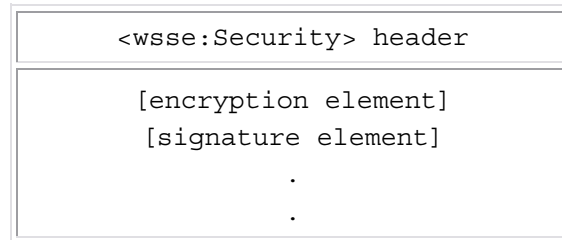

860

861

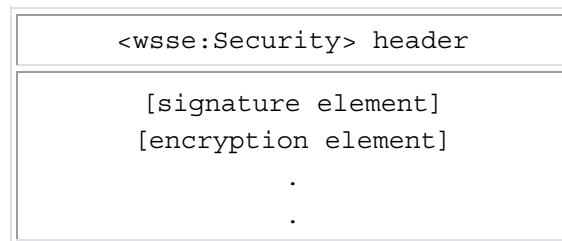

The Exclusive XML Canonicalization algorithm addresses the pitfalls of general canonicalization that can occur from *leaky* namespaces with pre-existing signatures.

862

863 Finally, if a producer wishes to sign a message before encryption, then following the ordering  
864 rules laid out in section 5, "Security Header", they SHOULD first prepend the signature element to  
865 the <wsse:Security> header, and then prepend the encryption element, resulting in a  
866 <wsse:Security> header that has the encryption element first, followed by the signature  
867 element:  
868

869 Likewise, if a producer wishes to sign a message after encryption, they SHOULD first prepend  
870 the encryption element to the <wsse:Security> header, and then prepend the signature  
871 element. This will result in a <wsse:Security> header that has the signature element first,  
872 followed by the encryption element:  
873  
874

875 The XML Digital Signature WG has defined two canonicalization algorithms: XML  
876 Canonicalization and Exclusive XML Canonicalization. To prevent confusion, the first is also  
877 called Inclusive Canonicalization. Neither one solves all possible problems that can arise. The  
878 following informal discussion is intended to provide guidance on the choice of which one to use  
879 in particular circumstances. For a more detailed and technically precise discussion of these  
880 issues see: [XML-C14N] and [EXC-C14N].  
881 There are two problems to be avoided. On the one hand, XML allows documents to be changed  
882 in various ways and still be considered equivalent. For example, duplicate namespace  
883 declarations can be removed or created. As a result, XML tools make these kinds of changes  
884 freely when processing XML. Therefore, it is vital that these equivalent forms match the same  
885 signature.  
886 On the other hand, if the signature simply covers something like xx:foo, its meaning may change  
887 if xx is redefined. In this case the signature does not prevent tampering. It might be thought that  
888 the problem could be solved by expanding all the values in line. Unfortunately, there are  
889 mechanisms like XPATH which consider xx="http://example.com/"; to be different from  
890 yy="http://example.com/"; even though both xx and yy are bound to the same namespace.  
891 The fundamental difference between the Inclusive and Exclusive Canonicalization is the  
892 namespace declarations which are placed in the output. Inclusive Canonicalization copies all the  
893 declarations that are currently in force, even if they are defined outside of the scope of the  
894 signature. It also copies any xml: attributes that are in force, such as xml:lang or xml:base.  
895 This guarantees that all the declarations you might make use of will be unambiguously specified.  
896 The problem with this is that if the signed XML is moved into another XML document which has  
897 other declarations, the Inclusive Canonicalization will copy them and the signature will be invalid.  
898 This can even happen if you simply add an attribute in a different namespace to the surrounding  
899 context.  
900 Exclusive Canonicalization tries to figure out what namespaces you are actually using and just  
901 copies those. Specifically, it copies the ones that are "visibly used", which means the ones that  
902

903 are a part of the XML syntax. However, it does not look into attribute values or element content,  
904 so the namespace declarations required to process these are not copied. For example  
905 if you had an attribute like `xx:foo="yy:bar"` it would copy the declaration for `xx`, but not `yy`. (This  
906 can even happen without your knowledge because XML processing tools will add `xsi:type` if  
907 you use a schema subtype.) It also does not copy the `xml:attributes` that are declared outside the  
908 scope of the signature.

909 Exclusive Canonicalization allows you to create a list of the namespaces that must be declared,  
910 so that it will pick up the declarations for the ones that are not visibly used. The only problem is  
911 that the software doing the signing must know what they are. In a typical SOAP software  
912 environment, the security code will typically be unaware of all the namespaces being used by  
913 the application in the message body that it is signing.

914 Exclusive Canonicalization is useful when you have a signed XML document that you wish to  
915 insert into other XML documents. A good example is a signed SAML assertion which might be  
916 inserted as a XML Token in the security header of various SOAP messages. The Issuer who  
917 signs the assertion will be aware of the namespaces being used and able to construct the list.  
918 The use of Exclusive Canonicalization will insure the signature verifies correctly every time.

919 Inclusive Canonicalization is useful in the typical case of signing part or all of the SOAP body in  
920 accordance with this specification. This will insure all the declarations fall under the signature,  
921 even though the code is unaware of what namespaces are being used. At the same time, it is  
922 less likely that the signed data (and signature element) will be inserted in some other XML  
923 document. Even if this is desired, it still may not be feasible for other reasons, for example there  
924 may be Id's with the same value defined in both XML documents.

925 In other situations it will be necessary to study the requirements of the application and the  
926 detailed operation of the canonicalization methods to determine which is appropriate.

927 This section is non-normative.

928

## 929 **8.2 Signing Messages**

930 The `<wsse:Security>` header block MAY be used to carry a signature compliant with the XML  
931 Signature specification within a SOAP Envelope for the purpose of signing one or more elements  
932 in the SOAP Envelope. Multiple signature entries MAY be added into a single SOAP Envelope  
933 within one `<wsse:Security>` header block. Producers SHOULD sign all important elements of  
934 the message, and careful thought must be given to creating a signing policy that requires signing  
935 of parts of the message that might legitimately be altered in transit.

936 SOAP applications MUST satisfy the following conditions:

937 A compliant implementation MUST be capable of processing the required elements defined in the  
938 XML Signature specification.

939 To add a signature to a `<wsse:Security>` header block, a `<ds:Signature>` element  
940 conforming to the XML Signature specification MUST be prepended to the existing content of the  
941 `<wsse:Security>` header block, in order to indicate to the receiver the correct order of  
942 operations. All the `<ds:Reference>` elements contained in the signature SHOULD refer to a  
943 resource within the enclosing SOAP envelope as described in the XML Signature specification.  
944 However, since the SOAP message exchange model allows intermediate applications to modify  
945 the Envelope (add or delete a header block; for example), XPath filtering does not always result  
946 in the same objects after message delivery. Care should be taken in using XPath filtering so that  
947 there is no subsequent validation failure due to such modifications.

948 The problem of modification by intermediaries (especially active ones) is applicable to more than  
949 just XPath processing. Digital signatures, because of canonicalization and digests, present  
950 particularly fragile examples of such relationships. If overall message processing is to remain  
951 robust, intermediaries must exercise care that the transformation algorithms used do not affect  
952 the validity of a digitally signed component.

953 Due to security concerns with namespaces, this specification strongly RECOMMENDS the use of  
954 the "Exclusive XML Canonicalization" algorithm or another canonicalization algorithm that  
955 provides equivalent or greater protection.

956 For processing efficiency it is RECOMMENDED to have the signature added and then the  
957 security token pre-pended so that a processor can read and cache the token before it is used.

### 958 **8.3 Signing Tokens**

959 It is often desirable to sign security tokens that are included in a message or even external to the  
960 message. The XML Signature specification provides several common ways for referencing  
961 information to be signed such as URIs, IDs, and XPath, but some token formats may not allow  
962 tokens to be referenced using URIs or IDs and XPaths may be undesirable in some situations.  
963 This specification allows different tokens to have their own unique reference mechanisms which  
964 are specified in their profile as extensions to the `<wsse:SecurityTokenReference>` element.  
965 This element provides a uniform referencing mechanism that is guaranteed to work with all token  
966 formats. Consequently, this specification defines a new reference option for XML Signature: the  
967 STR Dereference Transform.

968 This transform is specified by the URI `#STR-Transform` (Note that URI fragments are relative to  
969 this document's URI) and when applied to a `<wsse:SecurityTokenReference>` element it  
970 means that the output is the token referenced by the `<wsse:SecurityTokenReference>`  
971 element not the element itself.

972 As an overview the processing model is to echo the input to the transform except when a  
973 `<wsse:SecurityTokenReference>` element is encountered. When one is found, the element  
974 is not echoed, but instead, it is used to locate the token(s) matching the criteria and rules defined  
975 by the `<wsse:SecurityTokenReference>` element and echo it (them) to the output.

976 Consequently, the output of the transformation is the resultant sequence representing the input  
977 with any `<wsse:SecurityTokenReference>` elements replaced by the referenced security  
978 token(s) matched.

979 The following illustrates an example of this transformation which references a token contained  
980 within the message envelope:

```
981 ...
982 <wsse:SecurityTokenReference wsu:Id="Str1">
983   ...
984 </wsse:SecurityTokenReference>
985 ...
986 <ds:Signature xmlns:ds="http://www.w3.org/2000/09/xmldsig#">
987   <ds:SignedInfo>
988     ...
989     <ds:Reference URI="#Str1">
990       <ds:Transforms>
991         <ds:Transform
992           Algorithm="...#STR-Transform">
993           <wsse:TransformationParameters>
994             <ds:CanonicalizationMethod
995               Algorithm="http://www.w3.org/TR/2001/REC-xml-
996 c14n-20010315" />
997           </wsse:TransformationParameters>
998         </ds:Transform>
999         <ds:DigestMethod Algorithm=
1000           "http://www.w3.org/2000/09/xmldsig#sha1"/>
1001         <ds:DigestValue>...</ds:DigestValue>
1002       </ds:Reference>
1003     </ds:SignedInfo>
1004     <ds:SignatureValue></ds:SignatureValue>
1005   </ds:Signature>
1006 ...
1007
```

1008  
1009 The following describes the attributes and elements listed in the example above:  
1010 `/wsse:TransformationParameters`

1011 This element is used to wrap parameters for a transformation allows elements even from  
1012 the XML Signature namespace.

1013 */wsse:TransformationParameters/ds:Canonicalization*  
1014 This specifies the canonicalization algorithm to apply to the selected data.

1015 */wsse:TransformationParameters/{any}*  
1016 This is an extensibility mechanism to allow different (extensible) parameters to be  
1017 specified in the future. Unrecognized parameters SHOULD cause a fault.

1018 */wsse:TransformationParameters/@{any}*  
1019 This is an extensibility mechanism to allow additional attributes, based on schemas, to be  
1020 added to the element in the future. Unrecognized attributes SHOULD cause a fault.

1021

1022 The following is a detailed specification of the transformation.  
1023 The algorithm is identified by the URI: #STR-Transform  
1024 Transform Input:

- 1025 • The input is a node set. If the input is an octet stream, then it is automatically parsed; cf.  
1026 XML Digital Signature [XMLSIG].

1027 Transform Output:

- 1028 • The output is an octet stream.

1029 Syntax:

- 1030 • The transform takes a single mandatory parameter, a  
1031 `<ds:CanonicalizationMethod>` element, which is used to serialize the input node  
1032 set. Note, however, that the output may not be strictly in canonical form, per the  
1033 canonicalization algorithm; however, the output is canonical, in the sense that it is  
1034 unambiguous. However, because of syntax requirements in the XML Signature  
1035 definition, this parameter MUST be wrapped in a  
1036 `<wsse:TransformationParameters>` element.

1037 Processing Rules:

- 1038 • Let N be the input node set.
- 1039 • Let R be the set of all `<wsse:SecurityTokenReference>` elements in N.
- 1040 • For each  $R_i$  in R, let  $D_i$  be the result of dereferencing  $R_i$ .
- 1041 • If  $D_i$  cannot be determined, then the transform MUST signal a failure.
- 1042 • If  $D_i$  is an XML security token (e.g., a SAML assertion or a  
1043 `<wsse:BinarySecurityToken>` element), then let  $R_i'$  be  $D_i$ . Otherwise,  $D_i$  is a raw  
1044 binary security token; i.e., an octet stream. In this case, let  $R_i'$  be a node set consisting of  
1045 a `<wsse:BinarySecurityToken>` element, utilizing the same namespace prefix as  
1046 the `<wsse:SecurityTokenReference>` element  $R_i$ , with no `EncodingType` attribute,  
1047 a `ValueType` attribute identifying the content of the security token, and text content  
1048 consisting of the binary-encoded security token, with no white space.
- 1049 • Finally, employ the canonicalization method specified as a parameter to the transform to  
1050 serialize N to produce the octet stream output of this transform; but, in place of any  
1051 dereferenced `<wsse:SecurityTokenReference>` element  $R_i$  and its descendants,  
1052 process the dereferenced node set  $R_i'$  instead. During this step, canonicalization of the  
1053 replacement node set MUST be augmented as follows:
  - 1054 ○ Note: A namespace declaration `xmlns=""` MUST be emitted with every apex  
1055 element that has no namespace node declaring a value for the default  
1056 namespace; cf. XML Decryption Transform.

## 1057 **8.4 Signature Validation**

1058 The validation of a `<ds:Signature>` element inside an `<wsse:Security>` header block  
1059 SHALL fail if:

- 1060 • the syntax of the content of the element does not conform to this specification, or
- 1061 • the validation of the signature contained in the element fails according to the core  
1062 validation of the XML Signature specification [XMLSIG], or

- 1063       • the application applying its own validation policy rejects the message for some reason  
1064       (e.g., the signature is created by an untrusted key – verifying the previous two steps only  
1065       performs cryptographic validation of the signature).  
1066   If the validation of the signature element fails, applications MAY report the failure to the producer  
1067   using the fault codes defined in Section 12 Error Handling.

## 1068    **8.5 Example**

1069   The following sample message illustrates the use of integrity and security tokens. For this  
1070   example, only the message body is signed.

```
1071  
1072   <?xml version="1.0" encoding="utf-8"?>  
1073   <S11:Envelope xmlns:S11="..." xmlns:wsse="..." xmlns:wsu="..."  
1074   xmlns:ds="...">  
1075     <S11:Header>  
1076       <wsse:Security>  
1077          <wsse:BinarySecurityToken  
1078            ValueType="...#X509v3"  
1079            EncodingType="...#Base64Binary"  
1080            wsu:Id="X509Token">  
1081              MIIIEZzCCA9CgAwIBAgIQEmtJZc0rqrKh5i...  
1082          </wsse:BinarySecurityToken>  
1083          <ds:Signature>  
1084            <ds:SignedInfo>  
1085              <ds:CanonicalizationMethod Algorithm=  
1086                "http://www.w3.org/2001/10/xml-exc-c14n#" />  
1087              <ds:SignatureMethod Algorithm=  
1088                "http://www.w3.org/2000/09/xmldsig#rsa-sha1" />  
1089              <ds:Reference URI="#myBody">  
1090                <ds:Transforms>  
1091                  <ds:Transform Algorithm=  
1092                    "http://www.w3.org/2001/10/xml-exc-c14n#" />  
1093                </ds:Transforms>  
1094              <ds:DigestMethod Algorithm=  
1095                "http://www.w3.org/2000/09/xmldsig#sha1" />  
1096              <ds:DigestValue>EULddytSol...</ds:DigestValue>  
1097              </ds:Reference>  
1098            </ds:SignedInfo>  
1099            <ds:SignatureValue>  
1100              BL8jdfToEb11/vXcMZNNjPOV...  
1101            </ds:SignatureValue>  
1102            <ds:KeyInfo>  
1103              <wsse:SecurityTokenReference>  
1104                <wsse:Reference URI="#X509Token" />  
1105              </wsse:SecurityTokenReference>  
1106            </ds:KeyInfo>  
1107            </ds:Signature>  
1108          </wsse:Security>  
1109       </S11:Header>  
1110       <S11:Body wsu:Id="myBody">  
1111          <tru:StockSymbol xmlns:tru="http://www.fabrikam123.com/payloads">  
1112            QQQ  
1113          </tru:StockSymbol>  
1114       </S11:Body>  
1115     </S11:Envelope>
```

---

## 9 Encryption

1116

1117 This specification allows encryption of any combination of body blocks, header blocks, and any of  
1118 these sub-structures by either a common symmetric key shared by the producer and the recipient  
1119 or a symmetric key carried in the message in an encrypted form.  
1120 In order to allow this flexibility, this specification leverages the XML Encryption standard.  
1121 Specifically what this specification describes is how three elements (listed below and defined in  
1122 XML Encryption) can be used within the <wsse:Security> header block. When a producer or  
1123 an active intermediary encrypts portion(s) of a SOAP message using XML Encryption they MUST  
1124 prepend a sub-element to the <wsse:Security> header block. Furthermore, the encrypting  
1125 party MUST either prepend the sub-element to an existing <wsse:Security> header block for  
1126 the intended recipients or create a new <wsse:Security> header block and insert the sub-  
1127 element. The combined process of encrypting portion(s) of a message and adding one of these  
1128 sub-elements is called an encryption step hereafter. The sub-element MUST contain the  
1129 information necessary for the recipient to identify the portions of the message that it is able to  
1130 decrypt.  
1131 All compliant implementations MUST be able to support the XML Encryption standard [XMLENC].

### 1132 9.1 xenc:ReferenceList

1133 The <xenc:ReferenceList> element from XML Encryption [XMLENC] MAY be used to  
1134 create a manifest of encrypted portion(s), which are expressed as <xenc:EncryptedData>  
1135 elements within the envelope. An element or element content to be encrypted by this encryption  
1136 step MUST be replaced by a corresponding <xenc:EncryptedData> according to XML  
1137 Encryption. All the <xenc:EncryptedData> elements created by this encryption step  
1138 SHOULD be listed in <xenc:DataReference> elements inside one or more  
1139 <xenc:ReferenceList> element.  
1140 Although in XML Encryption [XMLENC], <xenc:ReferenceList> was originally designed to  
1141 be used within an <xenc:EncryptedKey> element (which implies that all the referenced  
1142 <xenc:EncryptedData> elements are encrypted by the same key), this specification allows  
1143 that <xenc:EncryptedData> elements referenced by the same <xenc:ReferenceList>  
1144 MAY be encrypted by different keys. Each encryption key can be specified in <ds:KeyInfo>  
1145 within individual <xenc:EncryptedData>.  
1146 A typical situation where the <xenc:ReferenceList> sub-element is useful is that the  
1147 producer and the recipient use a shared secret key. The following illustrates the use of this sub-  
1148 element:

1149  
1150  
1151  
1152  
1153  
1154  
1155  
1156  
1157  
1158  
1159  
1160  
1161  
1162  
1163  
1164  
1165  
1166

```
<S11:Envelope xmlns:S11="..." xmlns:wsse="..." xmlns:wsu="..."
xmlns:ds="..." xmlns:xenc="...">
  <S11:Header>
    <wsse:Security>
      <xenc:ReferenceList>
        <xenc:DataReference URI="#bodyID"/>
      </xenc:ReferenceList>
    </wsse:Security>
  </S11:Header>
  <S11:Body>
    <xenc:EncryptedData Id="bodyID">
      <ds:KeyInfo>
        <ds:KeyName>CN=Hiroshi Maruyama, C=JP</ds:KeyName>
      </ds:KeyInfo>
      <xenc:CipherData>
        <xenc:CipherValue>...</xenc:CipherValue>
      </xenc:CipherData>
    </xenc:EncryptedData>
  </S11:Body>
</S11:Envelope>
```

```
1167     </xenc:EncryptedData>
1168     </S11:Body>
1169 </S11:Envelope>
```

## 1170 **9.2 xenc:EncryptedKey**

1171 When the encryption step involves encrypting elements or element contents within a SOAP  
1172 envelope with a symmetric key, which is in turn to be encrypted by the recipient's key and  
1173 embedded in the message, <xenc:EncryptedKey> MAY be used for carrying such an  
1174 encrypted key. This sub-element SHOULD have a manifest, that is, an  
1175 <xenc:ReferenceList> element, in order for the recipient to know the portions to be  
1176 decrypted with this key. An element or element content to be encrypted by this encryption step  
1177 MUST be replaced by a corresponding <xenc:EncryptedData> according to XML Encryption.  
1178 All the <xenc:EncryptedData> elements created by this encryption step SHOULD be listed in  
1179 the <xenc:ReferenceList> element inside this sub-element.

1180 This construct is useful when encryption is done by a randomly generated symmetric key that is  
1181 in turn encrypted by the recipient's public key. The following illustrates the use of this element:

```
1182
1183 <S11:Envelope xmlns:S11="..." xmlns:wsse="..." xmlns:wsu="..."
1184 xmlns:ds="..." xmlns:xenc="...">
1185   <S11:Header>
1186     <wsse:Security>
1187       <xenc:EncryptedKey>
1188         ...
1189         <ds:KeyInfo>
1190           <wsse:SecurityTokenReference>
1191             <ds:X509IssuerSerial>
1192               <ds:X509IssuerName>
1193                 DC=ACMECorp, DC=com
1194               </ds:X509IssuerName>
1195             <ds:X509SerialNumber>12345678</ds:X509SerialNumber>
1196             </ds:X509IssuerSerial>
1197           </wsse:SecurityTokenReference>
1198         </ds:KeyInfo>
1199         ...
1200       </xenc:EncryptedKey>
1201     ...
1202   </wsse:Security>
1203 </S11:Header>
1204 <S11:Body>
1205   <xenc:EncryptedData Id="bodyID">
1206     <xenc:CipherData>
1207       <xenc:CipherValue>...</xenc:CipherValue>
1208     </xenc:CipherData>
1209   </xenc:EncryptedData>
1210 </S11:Body>
1211 </S11:Envelope>
```

1212  
1213 While XML Encryption specifies that <xenc:EncryptedKey> elements MAY be specified in  
1214 <xenc:EncryptedData> elements, this specification strongly RECOMMENDS that  
1215 <xenc:EncryptedKey> elements be placed in the <wsse:Security> header.

## 1216 **9.3 Processing Rules**

1217 Encrypted parts or using one of the sub-elements defined above MUST be in compliance with the  
1218 XML Encryption specification. An encrypted SOAP envelope MUST still be a valid SOAP  
1219 envelope. The message creator MUST NOT encrypt the <S11:Envelope>, <S12:Envelope>, <S11:Header>, <S12:Header>, or <S11:Body>, <S12:Body>  
1220 elements but MAY encrypt child elements of either the <S11:Header>, <S12:Header> and  
1221

1222 <S11:Body> or <S12:Body> elements. Multiple steps of encryption MAY be added into a  
1223 single <wsse:Security> header block if they are targeted for the same recipient.  
1224 When an element or element content inside a SOAP envelope (e.g. the contents of the  
1225 <S11:Body> or <S12:Body> elements) are to be encrypted, it MUST be replaced by an  
1226 <xenc:EncryptedData>, according to XML Encryption and it SHOULD be referenced from the  
1227 <xenc:ReferenceList> element created by this encryption step.

### 1228 9.3.1 Encryption

1229 The general steps (non-normative) for creating an encrypted SOAP message in compliance with  
1230 this specification are listed below (note that use of <xenc:ReferenceList> is  
1231 RECOMMENDED).

- 1232 • Create a new SOAP envelope.
- 1233 • Create a <wsse:Security> header
- 1234 • When an <xenc:EncryptedKey> is used, create a <xenc:EncryptedKey> sub-  
1235 element of the <wsse:Security> element. This <xenc:EncryptedKey> sub-  
1236 element SHOULD contain an <xenc:ReferenceList> sub-element, containing a  
1237 <xenc:DataReference> to each <xenc:EncryptedData> element that was  
1238 encrypted using that key.
- 1239 • Locate data items to be encrypted, i.e., XML elements, element contents within the target  
1240 SOAP envelope.
- 1241 • Encrypt the data items as follows: For each XML element or element content within the  
1242 target SOAP envelope, encrypt it according to the processing rules of the XML  
1243 Encryption specification [XMLENC]. Each selected original element or element content  
1244 MUST be removed and replaced by the resulting <xenc:EncryptedData> element.
- 1245 • The optional <ds:KeyInfo> element in the <xenc:EncryptedData> element MAY  
1246 reference another <ds:KeyInfo> element. Note that if the encryption is based on an  
1247 attached security token, then a <wsse:SecurityTokenReference> element SHOULD  
1248 be added to the <ds:KeyInfo> element to facilitate locating it.
- 1249 • Create an <xenc:DataReference> element referencing the generated  
1250 <xenc:EncryptedData> elements. Add the created <xenc:DataReference>  
1251 element to the <xenc:ReferenceList>.
- 1252 • Copy all non-encrypted data.

### 1253 9.3.2 Decryption

1254 On receiving a SOAP envelope containing encryption header elements, for each encryption  
1255 header element the following general steps should be processed (non-normative):

1256 Identify any decryption keys that are in the recipient's possession, then identifying any message  
1257 elements that it is able to decrypt.

1258 Locate the <xenc:EncryptedData> items to be decrypted (possibly using the  
1259 <xenc:ReferenceList>).

1260 Decrypt them as follows:

1261 For each element in the target SOAP envelope, decrypt it according to the processing rules of the  
1262 XML Encryption specification and the processing rules listed above.

1263 If the decryption fails for some reason, applications MAY report the failure to the producer using  
1264 the fault code defined in Section 12 Error Handling of this specification.

1265 It is possible for overlapping portions of the SOAP message to be encrypted in such a way that  
1266 they are intended to be decrypted by SOAP nodes acting in different Roles. In this case, the  
1267 <xenc:ReferenceList> or <xenc:EncryptedKey> elements identifying these encryption  
1268 operations will necessarily appear in different <wsse:Security> headers. Since SOAP does  
1269 not provide any means of specifying the order in which different Roles will process their  
1270 respective headers, this order is not specified by this specification and can only be determined by  
1271 a prior agreement.

1272

## 9.4 Decryption Transformation

1273

The ordering semantics of the `<wsse:Security>` header are sufficient to determine if signatures are over encrypted or unencrypted data. However, when a signature is included in one `<wsse:Security>` header and the encryption data is in another `<wsse:Security>` header, the proper processing order may not be apparent.

1274

1275

1276

1277

1278

1279

1280

If the producer wishes to sign a message that MAY subsequently be encrypted by an intermediary then the producer MAY use the Decryption Transform for XML Signature to explicitly specify the order of decryption.

---

## 10 Security Timestamps

1281

1282 It is often important for the recipient to be able to determine the *freshness* of security semantics.  
1283 In some cases, security semantics may be so *stale* that the recipient may decide to ignore it.  
1284 This specification does not provide a mechanism for synchronizing time. The assumption is that  
1285 time is trusted or additional mechanisms, not described here, are employed to prevent replay.  
1286 This specification defines and illustrates time references in terms of the `xsd:dateTime` type  
1287 defined in XML Schema. It is RECOMMENDED that all time references use this type. It is further  
1288 RECOMMENDED that all references be in UTC time. Implementations MUST NOT generate time  
1289 instants that specify leap seconds. If, however, other time types are used, then the `ValueType`  
1290 attribute (described below) MUST be specified to indicate the data type of the time format.  
1291 Requestors and receivers SHOULD NOT rely on other applications supporting time resolution  
1292 finer than milliseconds.

1293 The `<wsu:Timestamp>` element provides a mechanism for expressing the creation and  
1294 expiration times of the security semantics in a message.

1295 All times MUST be in UTC format as specified by the XML Schema type (`dateTime`). It should be  
1296 noted that times support time precision as defined in the XML Schema specification.

1297 The `<wsu:Timestamp>` element is specified as a child of the `<wsse:Security>` header and  
1298 may only be present at most once per header (that is, per SOAP actor/role).

1299 The ordering within the element is as illustrated below. The ordering of elements in the  
1300 `<wsu:Timestamp>` element is fixed and MUST be preserved by intermediaries.

1301 The schema outline for the `<wsu:Timestamp>` element is as follows:

1302

```
1303 <wsu:Timestamp wsu:Id="...">  
1304   <wsu:Created ValueType="...">...</wsu:Created>  
1305   <wsu:Expires ValueType="...">...</wsu:Expires>  
1306   ...  
1307 </wsu:Timestamp>
```

1308

1309 The following describes the attributes and elements listed in the schema above:

1310 `/wsu:Timestamp`

1311 This is the element for indicating message timestamps.

1312 `/wsu:Timestamp/wsue:Created`

1313 This represents the creation time of the security semantics. This element is optional, but  
1314 can only be specified once in a `<wsu:Timestamp>` element. Within the SOAP  
1315 processing model, creation is the instant that the info set is serialized for transmission.

1316 The creation time of the message SHOULD NOT differ substantially from its transmission  
1317 time. The difference in time should be minimized.

1318 `/wsu:Timestamp/wsue:Expires`

1319 This element represents the expiration of the security semantics. This is optional, but  
1320 can appear at most once in a `<wsu:Timestamp>` element. Upon expiration, the  
1321 requestor asserts that its security semantics are no longer valid. It is strongly  
1322 RECOMMENDED that recipients (anyone who processes this message) discard (ignore)  
1323 any message whose security semantics have passed their expiration. A Fault code  
1324 (`wsu:MessageExpired`) is provided if the recipient wants to inform the requestor that its  
1325 security semantics were expired. A service MAY issue a Fault indicating the security  
1326 semantics have expired.

1327 `/wsu:Timestamp/{any}`

1328 This is an extensibility mechanism to allow additional elements to be added to the  
1329 element. Unrecognized elements SHOULD cause a fault.

1330 `/wsu:Timestamp/@wsu:Id`

1331 This optional attribute specifies an XML Schema ID that can be used to reference this  
1332 element (the timestamp). This is used, for example, to reference the timestamp in a XML  
1333 Signature.

1334 */wsu:Timestamp/@{any}*

1335 This is an extensibility mechanism to allow additional attributes to be added to the  
1336 element. Unrecognized attributes SHOULD cause a fault.

1337 The expiration is relative to the requestor's clock. In order to evaluate the expiration time,  
1338 recipients need to recognize that the requestor's clock may not be synchronized to the recipient's  
1339 clock. The recipient, therefore, MUST make an assessment of the level of trust to be placed in  
1340 the requestor's clock, since the recipient is called upon to evaluate whether the expiration time is  
1341 in the past relative to the requestor's, not the recipient's, clock. The recipient may make a  
1342 judgment of the requestor's likely current clock time by means not described in this specification,  
1343 for example an out-of-band clock synchronization protocol. The recipient may also use the  
1344 creation time and the delays introduced by intermediate SOAP roles to estimate the degree of  
1345 clock skew.

1346 The following example illustrates the use of the `<wsu:Timestamp>` element and its content.

1347

```
1348 <S11:Envelope xmlns:S11="..." xmlns:wsse="..." xmlns:wsu="...">
```

```
1349 <S11:Header>
```

```
1350 <wsse:Security>
```

```
1351 <wsu:Timestamp wsu:Id="timestamp">
```

```
1352 <wsu:Created>2001-09-13T08:42:00Z</wsu:Created>
```

```
1353 <wsu:Expires>2001-10-13T09:00:00Z</wsu:Expires>
```

```
1354 </wsu:Timestamp>
```

```
1355 ...
```

```
1356 </wsse:Security>
```

```
1357 ...
```

```
1358 </S11:Header>
```

```
1359 <S11:Body>
```

```
1360 ...
```

```
1361 </S11:Body>
```

```
1362 </S11:Envelope>
```

1363

## 11 Extended Example

1364 The following sample message illustrates the use of security tokens, signatures, and encryption.  
1365 For this example, the timestamp and the message body are signed prior to encryption. The  
1366 decryption transformation is not needed as the signing/encryption order is specified within the  
1367 <wsse:Security> header.

1442         Type="http://www.w3.org/2001/04/xmlenc#Element "
1443         wsu:Id="enc1">
1444     (061) <xenc:EncryptionMethod
1445         Algorithm="http://www.w3.org/2001/04/xmlenc#tripleDES-
1446     cbc" />
1447     (062) <xenc:CipherData>
1448     (063) <xenc:CipherValue>d2FpbmdvbGRfE0lm4byV0...
1449     (064) </xenc:CipherValue>
1450     (065) </xenc:CipherData>
1451     (066) </xenc:EncryptedData>
1452     (067) </S11:Body>
1453     (068) </S11:Envelope>

```

1455 Let's review some of the key sections of this example:

1456 Lines (003)-(058) contain the SOAP message headers.

1457 Lines (004)-(057) represent the `<wsse:Security>` header block. This contains the security-related information for the message.

1458 Lines (005)-(008) specify the timestamp information. In this case it indicates the creation time of the security semantics.

1459 Lines (010)-(012) specify a security token that is associated with the message. In this case, it specifies an X.509 certificate that is encoded as Base64. Line (011) specifies the actual Base64 encoding of the certificate.

1460 Lines (013)-(026) specify the key that is used to encrypt the body of the message. Since this is a symmetric key, it is passed in an encrypted form. Line (014) defines the algorithm used to encrypt the key. Lines (015)-(018) specify the identifier of the key that was used to encrypt the symmetric key. Lines (019)-(022) specify the actual encrypted form of the symmetric key. Lines (023)-(025) identify the encryption block in the message that uses this symmetric key. In this case it is only used to encrypt the body (Id="enc1").

1470 Lines (027)-(056) specify the digital signature. In this example, the signature is based on the X.509 certificate. Lines (028)-(047) indicate what is being signed. Specifically, line (039) references the message body.

1473 Lines (048)-(050) indicate the actual signature value – specified in Line (043).

1474 Lines (052)-(054) indicate the key that was used for the signature. In this case, it is the X.509 certificate included in the message. Line (053) provides a URI link to the Lines (010)-(012).

1476 The body of the message is represented by Lines (059)-(067).

1477 Lines (060)-(066) represent the encrypted metadata and form of the body using XML Encryption.

1478 Line (060) indicates that the "element value" is being replaced and identifies this encryption. Line (061) specifies the encryption algorithm – Triple-DES in this case. Lines (063)-(064) contain the

1480 actual cipher text (i.e., the result of the encryption). Note that we don't include a reference to the  
1481 key as the key references this encryption – Line (024).

1482

## 12 Error Handling

1483

There are many circumstances where an *error* can occur while processing security information.

1484

For example:

1485

- Invalid or unsupported type of security token, signing, or encryption

1486

- Invalid or unauthenticated or unauthenticatable security token

1487

- Invalid signature

1488

- Decryption failure

1489

- Referenced security token is unavailable

1490

- Unsupported namespace

1491

If a service does not perform its normal operation because of the contents of the Security header, then that MAY be reported using SOAP's Fault Mechanism. This specification does not mandate that faults be returned as this could be used as part of a denial of service or cryptographic attack. We combine signature and encryption failures to mitigate certain types of attacks.

1492

If a failure is returned to a producer then the failure MUST be reported using the SOAP Fault

1493

mechanism. The following tables outline the predefined security fault codes. The "unsupported"

1494

classes of errors are as follows. Note that the reason text provided below is RECOMMENDED,

1495

but alternative text MAY be provided if more descriptive or preferred by the implementation. The

1496

tables below are defined in terms of SOAP 1.1. For SOAP 1.2, the Fault/Code/Value is

1497

*env:Sender* (as defined in SOAP 1.2) and the Fault/Code/Subcode/Value is the *faultcode* below

1498

and the Fault/Reason/Text is the *faultstring* below.

1499

1500

1501

1502

Error that occurred (faultstring)	Faultcode
An unsupported token was provided	wsse:UnsupportedSecurityToken
An unsupported signature or encryption algorithm was used	wsse:UnsupportedAlgorithm

1503

The "failure" class of errors are:

Error that occurred (faultstring)	faultcode
An error was discovered processing the <wsse:Security> header.	wsse:InvalidSecurity
An invalid security token was provided	wsse:InvalidSecurityToken
The security token could not be authenticated or authorized	wsse:FailedAuthentication
The signature or decryption was invalid	wsse:FailedCheck
Referenced security token could not be retrieved	wsse:SecurityTokenUnavailable

1504  
1505  
1506  
1507  
1508  
1509  
1510  
1511

## 13 Security Considerations

As stated in the Goals and Requirements section of this document, this specification is meant to provide extensible framework and flexible syntax, with which one could implement various security mechanisms. This framework and syntax by itself *does not provide any guarantee of security*. When implementing and using this framework and syntax, one must make every effort to ensure that the result is not vulnerable to any one of a wide range of attacks.

1512

### 13.1 General Considerations

1513  
1514  
1515  
1516  
1517

It is not feasible to provide a comprehensive list of security considerations for such an extensible set of mechanisms. A complete security analysis **MUST** be conducted on specific solutions based on this specification. Below we illustrate some of the security concerns that often come up with protocols of this type, but we stress that this *is not an exhaustive list of concerns*.

1518  
1519  
1520  
1521  
1522  
1523  
1524  
1525  
1526  
1527  
1528  
1529  
1530  
1531

- freshness guarantee (e.g., the danger of replay, delayed messages and the danger of relying on timestamps assuming secure clock synchronization)
- proper use of digital signature and encryption (signing/encrypting critical parts of the message, interactions between signatures and encryption), i.e., signatures on (content of) encrypted messages leak information when in plain-text)
- protection of security tokens (integrity)
- certificate verification (including revocation issues)
- the danger of using passwords without outmost protection (i.e. dictionary attacks against passwords, replay, insecurity of password derived keys, ...)
- the use of randomness (or strong pseudo-randomness)
- interaction between the security mechanisms implementing this standard and other system component
- man-in-the-middle attacks
- PKI attacks (i.e. identity mix-ups)

1532  
1533  
1534  
1535

There are other security concerns that one may need to consider in security protocols. The list above should not be used as a "check list" instead of a comprehensive security analysis. The next section will give a few details on some of the considerations in this list.

1536

### 13.2 Additional Considerations

1537

#### 13.2.1 Replay

1538  
1539  
1540  
1541  
1542  
1543  
1544  
1545  
1546  
1547  
1548

Digital signatures alone do not provide message authentication. One can record a signed message and resend it (a replay attack). It is strongly **RECOMMENDED** that messages include digitally signed elements to allow message recipients to detect replays of the message when the messages are exchanged via an open network. These can be part of the message or of the headers defined from other SOAP extensions. Four typical approaches are: Timestamp, Sequence Number, Expirations and Message Correlation. Signed timestamps **MAY** be used to keep track of messages (possibly by caching the most recent timestamp from a specific service) and detect replays of previous messages. It is **RECOMMENDED** that timestamps be cached for a given period of time, as a guideline, a value of five minutes can be used as a minimum to detect replays, and that timestamps older than that given period of time set be rejected in interactive scenarios.

## 1549 **13.2.2 Combining Security Mechanisms**

1550 This specification defines the use of XML Signature and XML Encryption in SOAP headers. As  
1551 one of the building blocks for securing SOAP messages, it is intended to be used in conjunction  
1552 with other security techniques. Digital signatures need to be understood in the context of other  
1553 security mechanisms and possible threats to an entity.  
1554 Implementers should also be aware of all the security implications resulting from the use of digital  
1555 signatures in general and XML Signature in particular. When building trust into an application  
1556 based on a digital signature there are other technologies, such as certificate evaluation, that must  
1557 be incorporated, but these are outside the scope of this document.  
1558 As described in XML Encryption, the combination of signing and encryption over a common data  
1559 item may introduce some cryptographic vulnerability. For example, encrypting digitally signed  
1560 data, while leaving the digital signature in the clear, may allow plain text guessing attacks.

## 1561 **13.2.3 Challenges**

1562 When digital signatures are used for verifying the claims pertaining to the sending entity, the  
1563 producer must demonstrate knowledge of the confirmation key. One way to achieve this is to use  
1564 a challenge-response type of protocol. Such a protocol is outside the scope of this document.  
1565 To this end, the developers can attach timestamps, expirations, and sequences to messages.

## 1566 **13.2.4 Protecting Security Tokens and Keys**

1567 Implementers should be aware of the possibility of a token substitution attack. In any situation  
1568 where a digital signature is verified by reference to a token provided in the message, which  
1569 specifies the key, it may be possible for an unscrupulous producer to later claim that a different  
1570 token, containing the same key, but different information was intended.  
1571 An example of this would be a user who had multiple X.509 certificates issued relating to the  
1572 same key pair but with different attributes, constraints or reliance limits. Note that the signature of  
1573 the token by its issuing authority does not prevent this attack. Nor can an authority effectively  
1574 prevent a different authority from issuing a token over the same key if the user can prove  
1575 possession of the secret.  
1576 The most straightforward counter to this attack is to insist that the token (or its unique identifying  
1577 data) be included under the signature of the producer. If the nature of the application is such that  
1578 the contents of the token are irrelevant, assuming it has been issued by a trusted authority, this  
1579 attack may be ignored. However because application semantics may change over time, best  
1580 practice is to prevent this attack.  
1581 Requestors should use digital signatures to sign security tokens that do not include signatures (or  
1582 other protection mechanisms) to ensure that they have not been altered in transit. It is strongly  
1583 RECOMMENDED that all relevant and immutable message content be signed by the producer.  
1584 Receivers SHOULD only consider those portions of the document that are covered by the  
1585 producer's signature as being subject to the security tokens in the message. Security tokens  
1586 appearing in `<wsse:Security>` header elements SHOULD be signed by their issuing authority  
1587 so that message receivers can have confidence that the security tokens have not been forged or  
1588 altered since their issuance. It is strongly RECOMMENDED that a message producer sign any  
1589 `<wsse:SecurityToken>` elements that it is confirming and that are not signed by their issuing  
1590 authority.  
1591 When a requester provides, within the request, a Public Key to be used to encrypt the response,  
1592 it is possible that an attacker in the middle may substitute a different Public Key, thus allowing the  
1593 attacker to read the response. The best way to prevent this attack is to bind the encryption key in  
1594 some way to the request. One simple way of doing this is to use the same key pair to sign the  
1595 request as to encrypt the response. However, if policy requires the use of distinct key pairs for  
1596 signing and encryption, then the Public Key provided in the request should be included under the  
1597 signature of the request.

1598 **13.2.5 Protecting Timestamps and Ids**

1599 In order to *trust* `wsu:Id` attributes and `<wsu:Timestamp>` elements, they SHOULD be signed  
1600 using the mechanisms outlined in this specification. This allows readers of the IDs and  
1601 timestamps information to be certain that the IDs and timestamps haven't been forged or altered  
1602 in any way. It is strongly RECOMMENDED that IDs and timestamp elements be signed.

1603  
1604 This section is non-normative.

1605

---

## 14 Interoperability Notes

1606

Based on interoperability experiences with this and similar specifications, the following list highlights several common areas where interoperability issues have been discovered. Care should be taken when implementing to avoid these issues. It should be noted that some of these may seem "obvious", but have been problematic during testing.

1607

1608

1609

1610

1611

- **Key Identifiers:** Make sure you understand the algorithm and how it is applied to security tokens.

1612

1613

1614

- **EncryptedKey:** The `<xenc:EncryptedKey>` element from XML Encryption requires a Type attribute whose value is one of a pre-defined list of values. Ensure that a correct value is used.

1615

1616

1617

- **Encryption Padding:** The XML Encryption random block cipher padding has caused issues with certain decryption implementations; be careful to follow the specifications exactly.

1618

1619

1620

1621

1622

- **IDs:** The specification recognizes three specific ID elements: the global `wsu:Id` attribute and the local `Id` attributes on XML Signature and XML Encryption elements (because the latter two do not allow global attributes). If any other element does not allow global attributes, it cannot be directly signed using an ID reference. Note that the global attribute `wsu:Id` MUST carry the namespace specification.

1623

1624

- **Time Formats:** This specification uses a restricted version of the XML Schema `xsd:dateTime` element. Take care to ensure compliance with the specified restrictions.

1625

1626

- **Byte Order Marker (BOM):** Some implementations have problems processing the BOM marker. It is suggested that usage of this be optional.

1627

1628

1629

- **SOAP, WSDL, HTTP:** Various interoperability issues have been seen with incorrect SOAP, WSDL, and HTTP semantics being applied. Care should be taken to carefully adhere to these specifications and any interoperability guidelines that are available.

1630

This section is non-normative.

1631

---

## 15 Privacy Considerations

1632 In the context of this specification, we are only concerned with potential privacy violation by the  
1633 security elements defined here. Privacy of the content of the payload message is out of scope.  
1634 Producers or sending applications should be aware that claims, as collected in security tokens,  
1635 are typically personal information, and should thus only be sent according to the producer's  
1636 privacy policies. Future standards may allow privacy obligations or restrictions to be added to this  
1637 data. Unless such standards are used, the producer must ensure by out-of-band means that the  
1638 recipient is bound to adhering to all restrictions associated with the data, and the recipient must  
1639 similarly ensure by out-of-band means that it has the necessary consent for its intended  
1640 processing of the data.  
1641 If claim data are visible to intermediaries, then the policies must also allow the release to these  
1642 intermediaries. As most personal information cannot be released to arbitrary parties, this will  
1643 typically require that the actors are referenced in an identifiable way; such identifiable references  
1644 are also typically needed to obtain appropriate encryption keys for the intermediaries.  
1645 If intermediaries add claims, they should be guided by their privacy policies just like the original  
1646 producers.  
1647 Intermediaries may also gain traffic information from a SOAP message exchange, e.g., who  
1648 communicates with whom at what time. Producers that use intermediaries should verify that  
1649 releasing this traffic information to the chosen intermediaries conforms to their privacy policies.  
1650 This section is non-normative.

## Appendix A: Utility Elements and Attributes

1706  
1707  
1708  
1709  
1710

These specifications define several elements, attributes, and attribute groups which can be re-used by other specifications. This appendix provides an overview of these *utility* components. It should be noted that the detailed descriptions are provided in the specification and this appendix will reference these sections as well as calling out other aspects not documented in the specification.

1711

### A.1. Identification Attribute

1712  
1713  
1714  
1715  
1716  
1717  
1718  
1719  
1720  
1721  
1722  
1723  
1724  
1725  
1726  
1727

There are many situations where elements within SOAP messages need to be referenced. For example, when signing a SOAP message, selected elements are included in the signature. XML Schema Part 2 provides several built-in data types that may be used for identifying and referencing elements, but their use requires that consumers of the SOAP message either have or are able to obtain the schemas where the identity or reference mechanisms are defined. In some circumstances, for example, intermediaries, this can be problematic and not desirable. Consequently a mechanism is required for identifying and referencing elements, based on the SOAP foundation, which does not rely upon complete schema knowledge of the context in which an element is used. This functionality can be integrated into SOAP processors so that elements can be identified and referred to without dynamic schema discovery and processing. This specification specifies a namespace-qualified global attribute for identifying an element which can be applied to any element that either allows arbitrary attributes or specifically allows this attribute. This is a general purpose mechanism which can be re-used as needed. A detailed description can be found in Section 4.0 ID References.

This section is non-normative.

1728

### A.2. Timestamp Elements

1729  
1730  
1731  
1732  
1733  
1734  
1735  
1736  
1737  
1738

The specification defines XML elements which may be used to express timestamp information such as creation and expiration. While defined in the context of message security, these elements can be re-used wherever these sorts of time statements need to be made. The elements in this specification are defined and illustrated using time references in terms of the *dateTime* type defined in XML Schema. It is RECOMMENDED that all time references use this type for interoperability. It is further RECOMMENDED that all references be in UTC time for increased interoperability. If, however, other time types are used, then the `valueType` attribute MUST be specified to indicate the data type of the time format. The following table provides an overview of these elements:

Element	Description
<wsu:Created>	This element is used to indicate the creation time associated with the enclosing context.
<wsu:Expires>	This element is used to indicate the expiration time associated with the enclosing context.

1739  
1740  
1741  
1742  
1743

A detailed description can be found in Section 10.

This section is non-normative.

1744 **A.3. General Schema Types**

1745 The schema for the utility aspects of this specification also defines some general purpose  
1746 schema elements. While these elements are defined in this schema for use with this  
1747 specification, they are general purpose definitions that may be used by other specifications as  
1748 well.

1749 Specifically, the following schema elements are defined and can be re-used:  
1750

Schema Element	Description
wsu:commonAtts attribute group	This attribute group defines the common attributes recommended for elements. This includes the wsu:Id attribute as well as extensibility for other namespace qualified attributes.
wsu:AttributedDateTime type	This type extends the XML Schema dateTime type to include the common attributes.
wsu:AttributedURI type	This type extends the XML Schema anyURI type to include the common attributes.

1751  
1752 This section is non-normative.  
1753

1754

## Appendix B: SecurityTokenReference Model

1755 This appendix provides a non-normative overview of the usage and processing models for the  
1756 `<wsse:SecurityTokenReference>` element.

1757 There are several motivations for introducing the `<wsse:SecurityTokenReference>`  
1758 element:

1759 The XML Signature reference mechanisms are focused on "key" references rather than general  
1760 token references.

1761 The XML Signature reference mechanisms utilize a fairly closed schema which limits the  
1762 extensibility that can be applied.

1763 There are additional types of general reference mechanisms that are needed, but are not covered  
1764 by XML Signature.

1765 There are scenarios where a reference may occur outside of an XML Signature and the XML  
1766 Signature schema is not appropriate or desired.

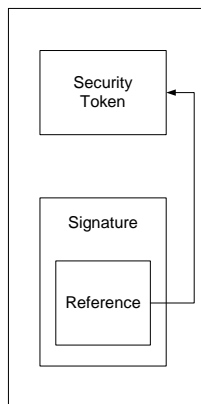

1767 The XML Signature references may include aspects (e.g. transforms) that may not apply to all  
1768 references.

1769

1770 The following use cases drive the above motivations:

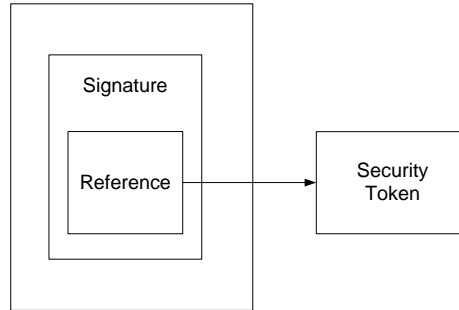

1771 **Local Reference** – A security token, that is included in the message in the `<wsse:Security>`  
1772 header, is associated with an XML Signature. The figure below illustrates this:

1773

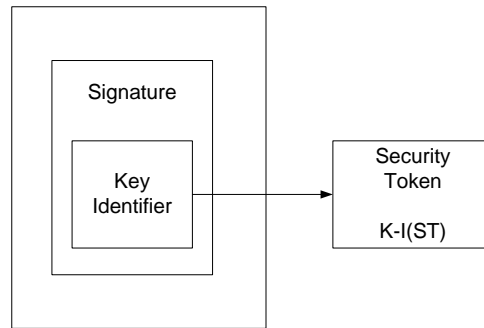

1774  
1775  
1776

**Remote Reference** – A security token, that is not included in the message but may be available at a specific URI, is associated with an XML Signature. The figure below illustrates this:

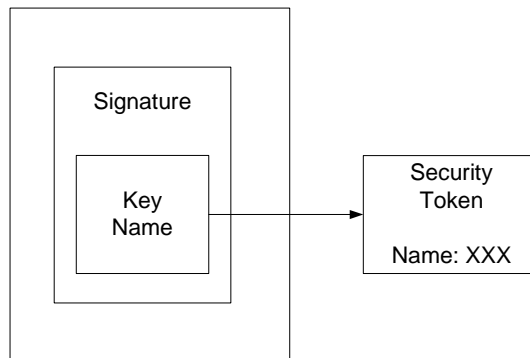

1777  
1778  
1779  
1780

**Key Identifier** – A security token, which is associated with an XML Signature and identified using a known value that is the result of a well-known function of the security token (defined by the token format or profile). The figure below illustrates this where the token is located externally:

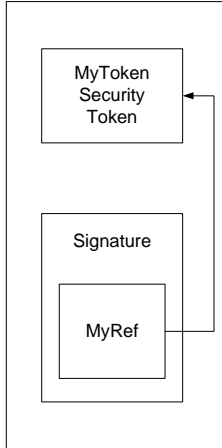

1781  
1782  
1783  
1784

**Key Name** – A security token is associated with an XML Signature and identified using a known value that represents a "name" assertion within the security token (defined by the token format or profile). The figure below illustrates this where the token is located externally:

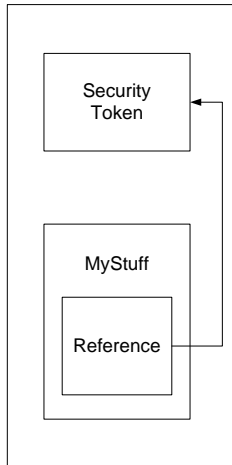

1785  
1786  
1787  
1788  
1789

**Format-Specific References** – A security token is associated with an XML Signature and identified using a mechanism specific to the token (rather than the general mechanisms described above). The figure below illustrates this:

1790 **Non-Signature References** – A message may contain XML that does not represent an XML  
 1791 signature, but may reference a security token (which may or may not be included in the  
 1792 message). The figure below illustrates this:

1793  
 1794  
 1795 All conformant implementations **MUST** be able to process the  
 1796 `<wsse:SecurityTokenReference>` element. However, they are not required to support all of  
 1797 the different types of references.  
 1798 The reference **MAY** include a *ValueType* attribute which provides a "hint" for the type of desired  
 1799 token.  
 1800 If multiple sub-elements are specified, together they describe the reference for the token.  
 1801 There are several challenges that implementations face when trying to interoperate:  
 1802 **ID References** – The underlying XML referencing mechanism using the XML base type of ID  
 1803 provides a simple straightforward XML element reference. However, because this is an XML  
 1804 type, it can be bound to *any* attribute. Consequently in order to process the IDs and references  
 1805 requires the recipient to *understand* the schema. This may be an expensive task and in the  
 1806 general case impossible as there is no way to know the "schema location" for a specific  
 1807 namespace URI.  
 1808 **Ambiguity** – The primary goal of a reference is to uniquely identify the desired token. ID  
 1809 references are, by definition, unique by XML. However, other mechanisms such as "principal  
 1810 name" are not required to be unique and therefore such references may be unique.  
 1811 The XML Signature specification defines a `<ds:KeyInfo>` element which is used to provide  
 1812 information about the "key" used in the signature. For token references within signatures, it is  
 1813 **RECOMMENDED** that the `<wsse:SecurityTokenReference>` be placed within the  
 1814 `<ds:KeyInfo>`. The XML Signature specification also defines mechanisms for referencing keys  
 1815 by identifier or passing specific keys. As a rule, the specific mechanisms defined in WSS: SOAP  
 1816 Message Security or its profiles are preferred over the mechanisms in XML Signature.  
 1817 The following provides additional details on the specific reference mechanisms defined in WSS:  
 1818 SOAP Message Security:  
 1819 **Direct References** – The `<wsse:Reference>` element is used to provide a URI reference to  
 1820 the security token. If only the fragment is specified, then it references the security token within

1821 the document whose `wsu:Id` matches the fragment. For non-fragment URIs, the reference is to  
1822 a [potentially external] security token identified using a URI. There are no implied semantics  
1823 around the processing of the URI.

1824 **Key Identifiers** – The `<wsse:KeyIdentifier>` element is used to reference a security token  
1825 by specifying a known value (identifier) for the token, which is determined by applying a special  
1826 *function* to the security token (e.g. a hash of key fields). This approach is typically unique for the  
1827 specific security token but requires a profile or token-specific function to be specified. The  
1828 `ValueType` attribute defines the type of key identifier and, consequently, identifies the type of  
1829 token referenced. The `EncodingType` attribute specifies how the unique value (identifier) is  
1830 encoded. For example, a hash value may be encoded using base 64 encoding (the default).

1831 **Key Names** – The `<ds:KeyName>` element is used to reference a security token by specifying a  
1832 specific value that is used to *match* an identity assertion within the security token. This is a  
1833 subset match and may result in multiple security tokens that match the specified name. While  
1834 XML Signature doesn't imply formatting semantics, WSS: SOAP Message Security  
1835 RECOMMENDS that X.509 names be specified.

1836 It is expected that, where appropriate, profiles define if and how the reference mechanisms map  
1837 to the specific token profile. Specifically, the profile should answer the following questions:

- 1838 • What types of references can be used?
- 1839 • How "Key Name" references map (if at all)?
- 1840 • How "Key Identifier" references map (if at all)?
- 1841 • Are there any additional profile or format-specific references?

## Appendix C: Revision History

Rev	Date	What
01	20-Sep-02	Initial draft based on input documents and editorial review
02	24-Oct-02	Update with initial comments (technical and grammatical)
03	03-Nov-02	Feedback updates
04	17-Nov-02	Feedback updates
05	02-Dec-02	Feedback updates
06	08-Dec-02	Feedback updates
07	11-Dec-02	Updates from F2F
08	12-Dec-02	Updates from F2F
14	03-Jun-03	Completed these pending issues - 62, 69, 70, 72, 74, 84, 90, 94, 95, 96, 97, 98, 99, 101, 102, 103, 106, 107, 108, 110, 111
15	18-Jul-03	Completed these pending issues – 78, 82, 104, 105, 109, 111, 113
16	26-Aug-03	Completed these pending issues - 99, 128, 130, 132, 134
18	15-Dec-03	Editorial Updates based on Issue List #30
19	29-Dec-03	Editorial Updates based on Issue List #31
20	14-Jan-04	Completed issue 241 and feedback updates
21	19-Jan-04	Editorial corrections for name space and document name
22	17-Feb-04	Editorial changes per Karl Best

## Appendix D: Notices

1848 OASIS takes no position regarding the validity or scope of any intellectual property or other rights  
1849 that might be claimed to pertain to the implementation or use of the technology described in this  
1850 document or the extent to which any license under such rights might or might not be available;  
1851 neither does it represent that it has made any effort to identify any such rights. Information on  
1852 OASIS's procedures with respect to rights in OASIS specifications can be found at the OASIS  
1853 website. Copies of claims of rights made available for publication and any assurances of licenses  
1854 to be made available, or the result of an attempt made to obtain a general license or permission  
1855 for the use of such proprietary rights by implementers or users of this specification, can be  
1856 obtained from the OASIS Executive Director.

1857 OASIS invites any interested party to bring to its attention any copyrights, patents or patent  
1858 applications, or other proprietary rights which may cover technology that may be required to  
1859 implement this specification. Please address the information to the OASIS Executive Director.
